EDAN65: Compilers

Introduction and Overview

Görel Hedin

Revised: 2024-09-02

Instructors

Lectures

- Prof. Görel Hedin

Programming assignments and lab sessions

- Idriss Riouak
- Anton Risberg Alaküla
- Anton Skorup
- Dag Hemberg

Course registration

Confirm that you will take the course by signing list

Register in LADOK this week

Sign up for lab session, by **Thursday, Sep 5**

Prerequisites

- Object-oriented programming, Java
  - Assignment 0 includes some details on Java to fresh up
- Simple algorithms and data structures
  (recursion, trees, lists, hash tables, …)

Course information

Web site: https://cs.lth.se/edan65

- read the Week by Week page to find out what to do each week.
- Lecture slides, readings, assignments, exercises, quizzes
- Material added continuously during the course
- No handouts – print yourself if you want it on paper

Textbook

- A. W. Appel, Jens Palsberg: Modern Compiler Implementation in Java, 2nd Edition, Cambridge University Press, 2002, ISBN: 0-521-82060-X
- Available as on-line e-book through Lund University
- Only part of the book is used. Covers only part of the course.

Moodle: Forum, online quizzes

Course structure

- **Lectures**, Mon 15-17, Tue 13-15 (+ Thu 10-12 week 1)
- **Assignment 0**, for freshing up on Unix, Java, and JUnit, and understanding the build system Gradle. Working with Git. Do on your own.
- **Assignment 1-6**. Mandatory.
  - **Work in pairs**. Form pairs in the break. Or use the forum.
  - **Heavy**. Lab sessions for getting approved and getting help if you are stuck.
  - Wed 8-10, Wed 10-12, Thu 8-10, Thu 10-12. **Sign up by Thursday Sep 5**
  - Lab sessions start next week (but start this week on your work)
  - Assignments **prerequisite for doing exam**
  - **Make sure the TAs note your presence at the lab session.** If you get stuck, you can get your assignment approved the next week (if you were present at the ordinary session). Email Görel for exemption due to illness.
- **Lecture quizzes**
  - Do on your own. (In Moodle.)
- **Exercises**
  - Do on your own or with your partner. (Book exercises without solutions + separate exercises with solutions)
- **Exam** – sign up in advance through the LTH system
  - Exam: Tuesday, Oct 29, 2024, 14-19. Kårhuset, Gasquesalen
  - Retake: April 2025.

Working with the assignments

- Collaborating with your partner, git repos on coursegit.cs.lth.se (see moodle)
  - in the **same** repository (recommended)
    - sit together, alternate who commits, **commit often**
    - git history should show progression during solving the assignment
    - if you commit from the same account, switch which account you use for the next assignment
  - in **separate** repositories
    - looser collaboration, help each other out if needed, compare solutions to get new insights, sync before lab session
    - **commit often**, git history should show progression during solving the assignment
  - Important: you need hands-on experience from all parts - you should be able to run and explain all parts of the solution

- If you (and your partner) get stuck before your lab session
  - ask on the forum
    - you are encouraged to give answers to other students on the forum (for general advice, small examples, but not full solutions)

- "Self-grading" web service:
  Drop in your compiler jar file and run our tests.
  Available for labs 2-6.

Estimated typical effort for assignments

A0: Unix, Java, Gradle, Git	1-4 hours	do on your own
A1: Scanning	5 hours	mandatory
A2: Parsing	15 hours	mandatory
A3: Visitors, aspects	12 hours	mandatory
A4: Semantic analysis	18 hours	mandatory
A5: Interpreter	15 hours	mandatory
A6: Code generator	12 hours	mandatory

Student representatives

- **Who?** 2 students.
- **During the course**: listen to your peers. Give feedback to instructor if relevant.
- **After the course**: participate in discussion of course evaluation results (with instructor).

Why learn compiler construction?

Why learn compiler construction?

It is about language tooling

- Understand how the language tools you use work (editors, compilers, transpilers, interpreters, ...)
- A compiler is just one example of a language tool. But it includes all the major techniques used for any software language processing.

Languages are everywhere in software

- Many software projects use some kind of domain-specific language, e.g., for configuration or describing input.

Fundamental theory and concepts

- Compiler theory: fundamental to computer science
- Essential for understanding programming languages

A traditional compiler

A traditional compiler

EXAMPLE:

```
...
csum = a + b + 1;
...
```

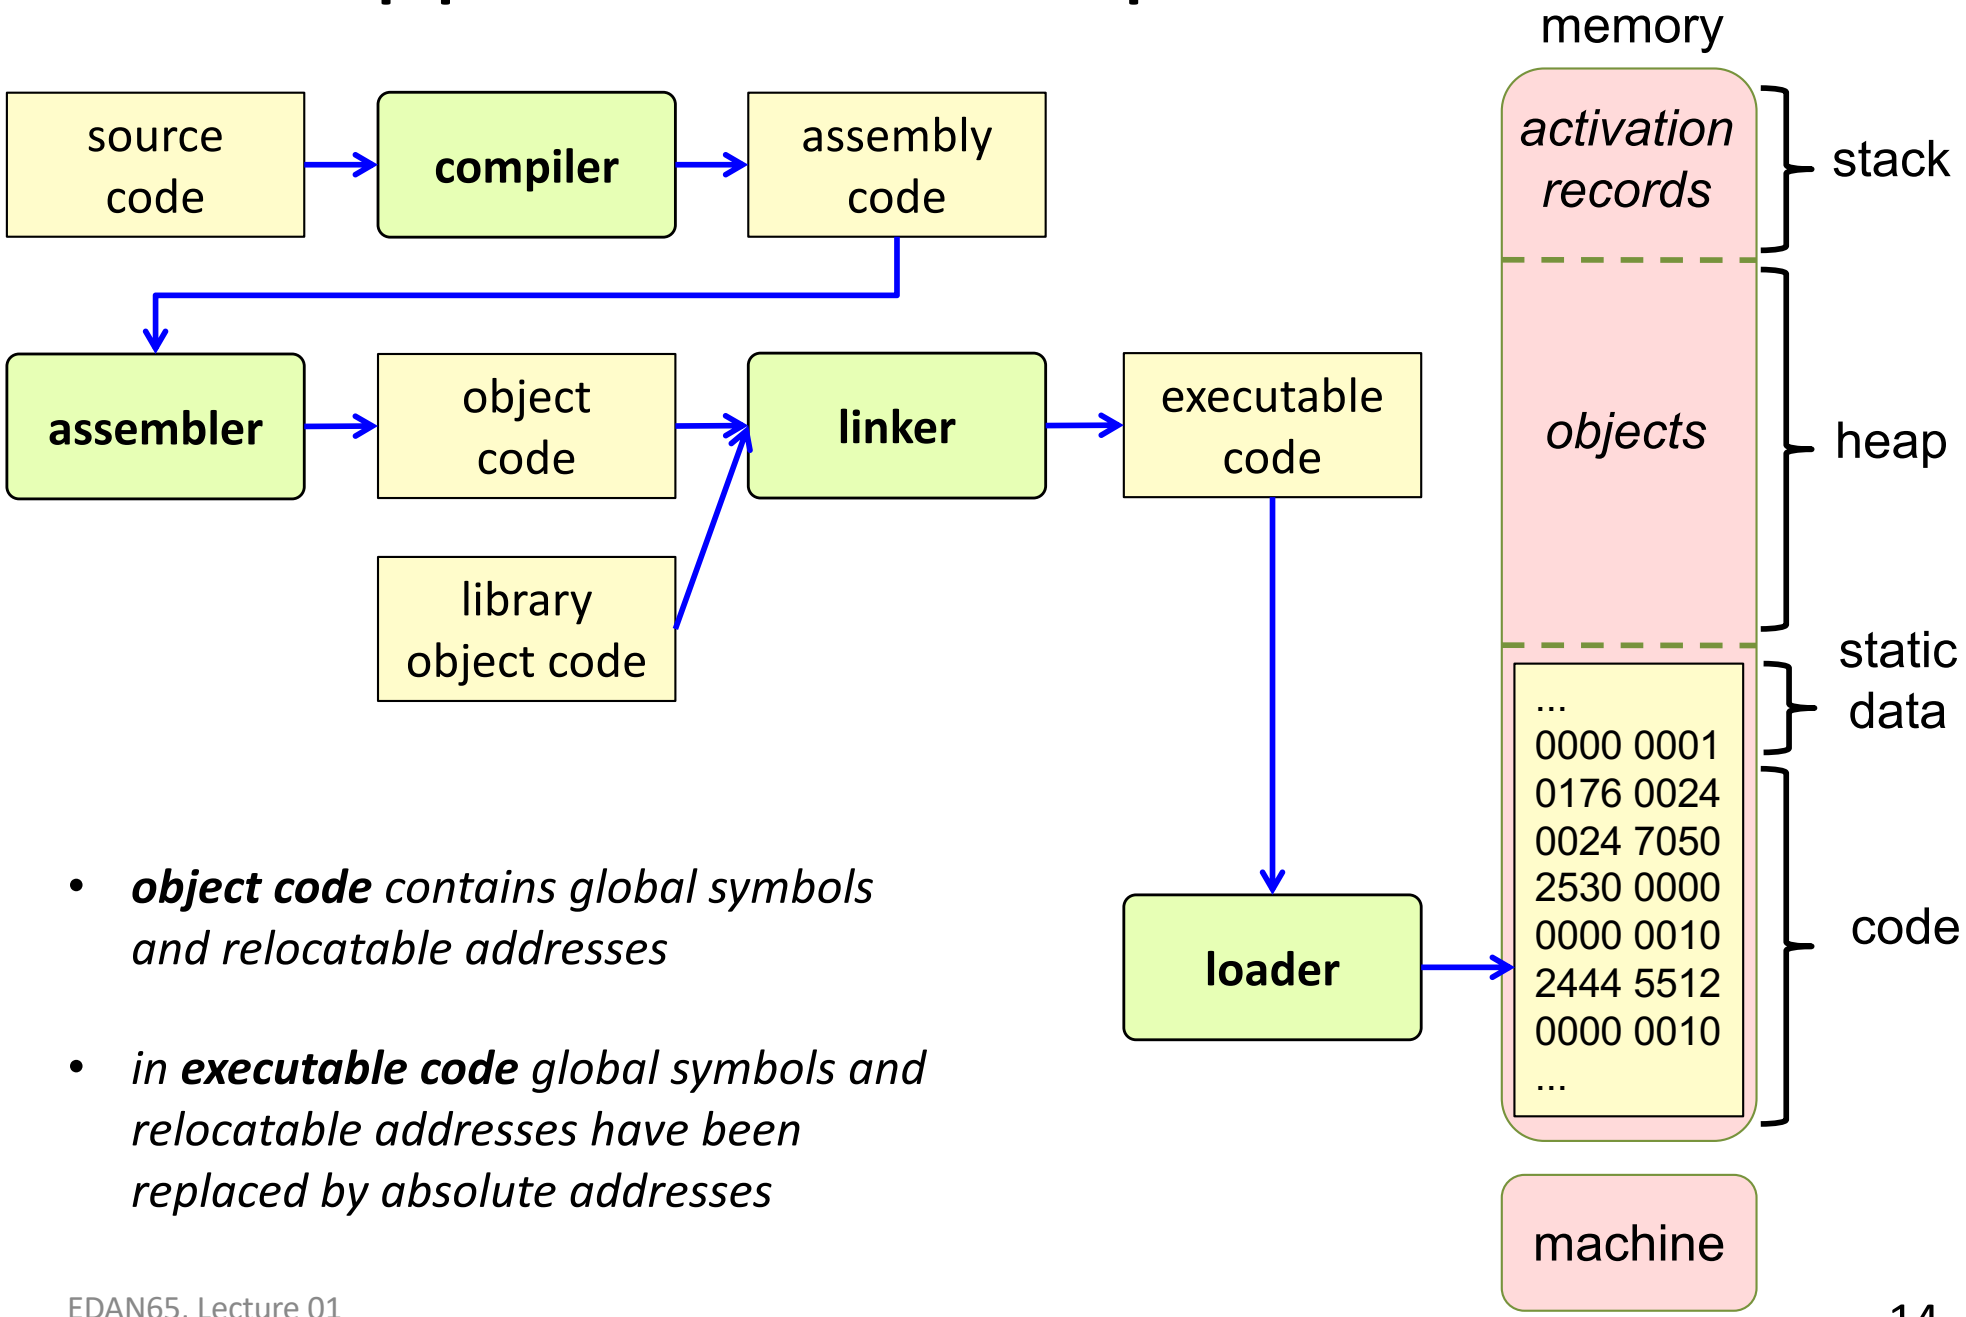
compiler

```
        .data
a:      .long   0
b:      .long   0
csum:   .long   0

        .code
        ...
        movl    a, %eax
        addl    b, %eax
        addl    $1, %eax
        movl    %eax, csum
        ...
```

What happens after compilation?

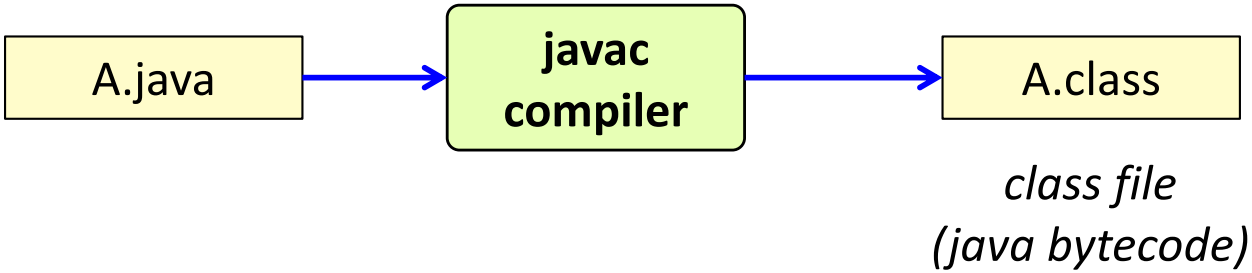
What happens after compilation?



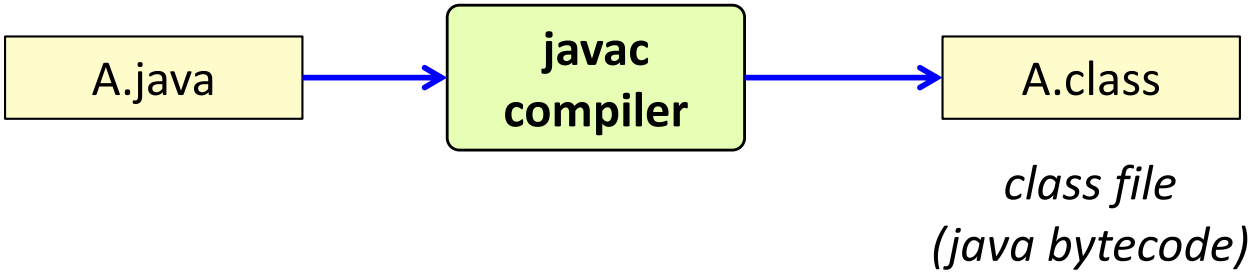
- ***object code*** *contains global symbols and relocatable addresses*
- *in* ***executable code*** *global symbols and relocatable addresses have been replaced by absolute addresses*

What about Java?

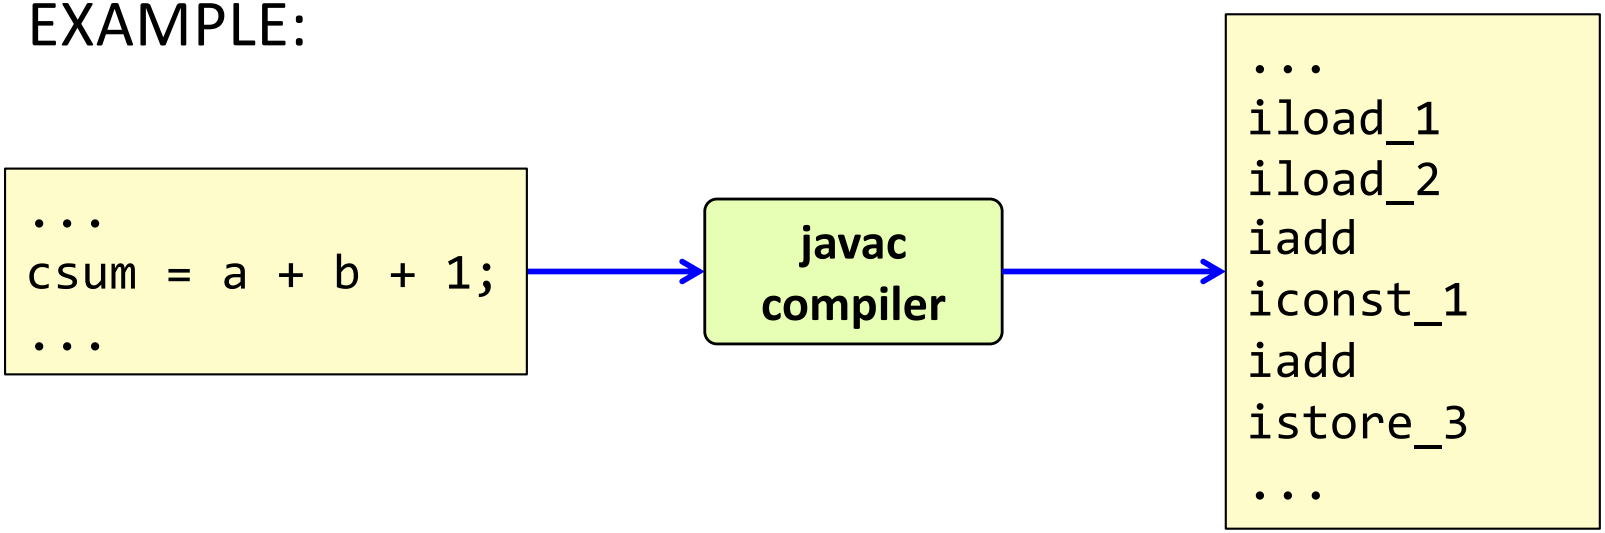
What about Java?



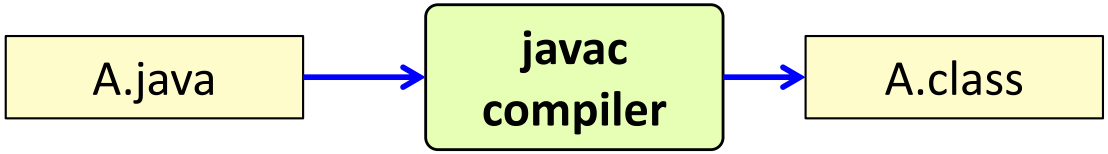
What about Java?



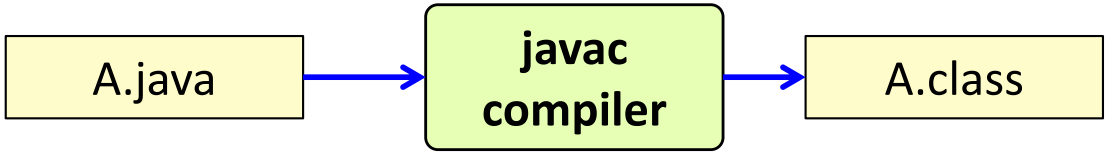
EXAMPLE:

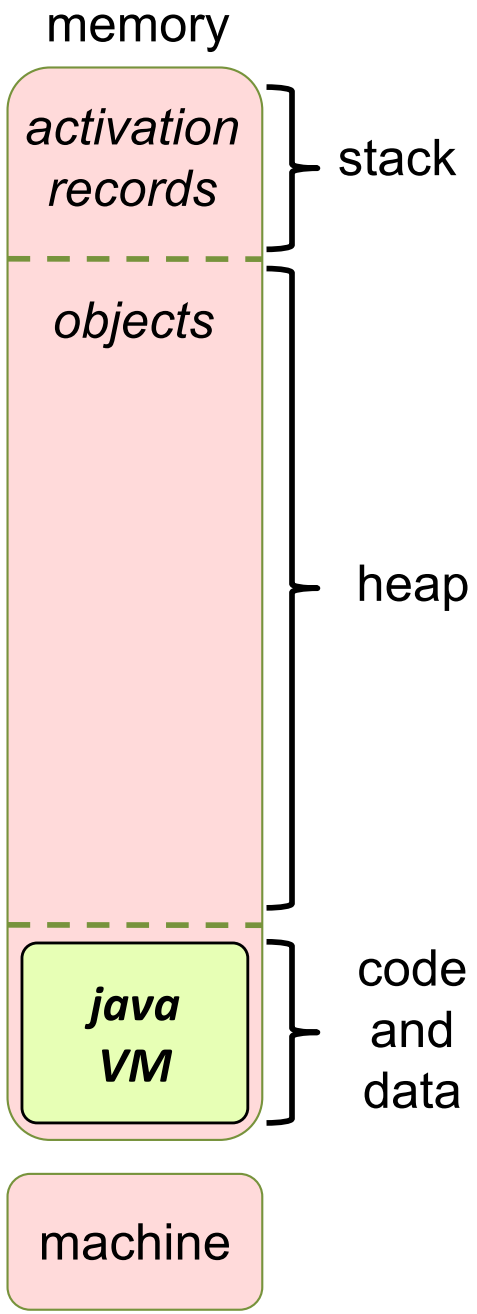


Running Java code?

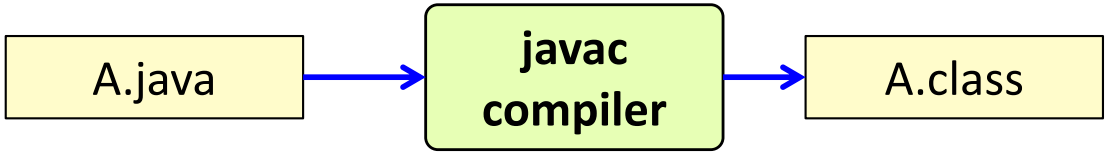


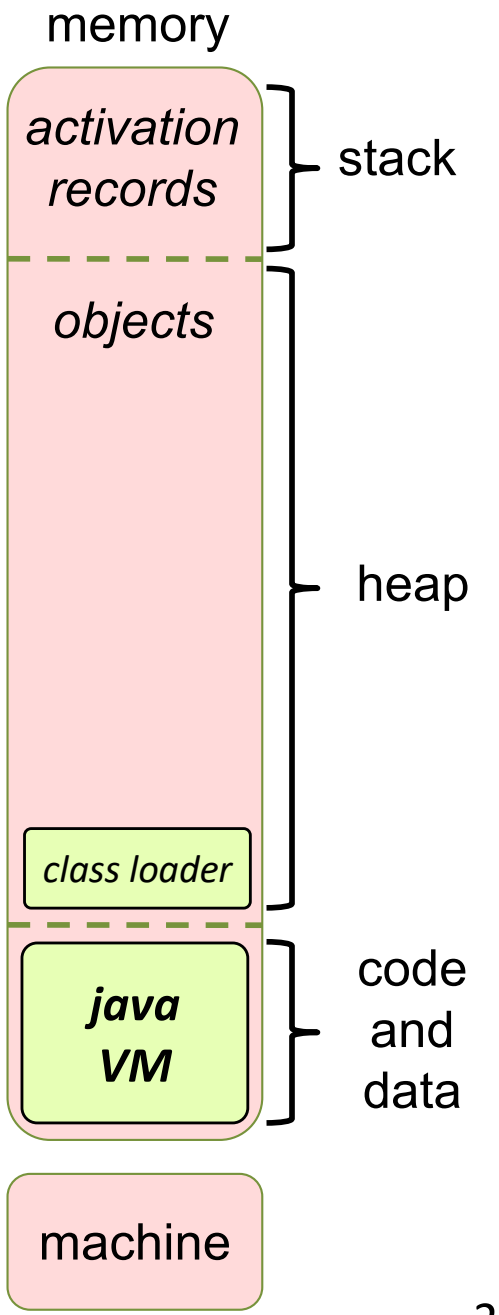
Running Java code?



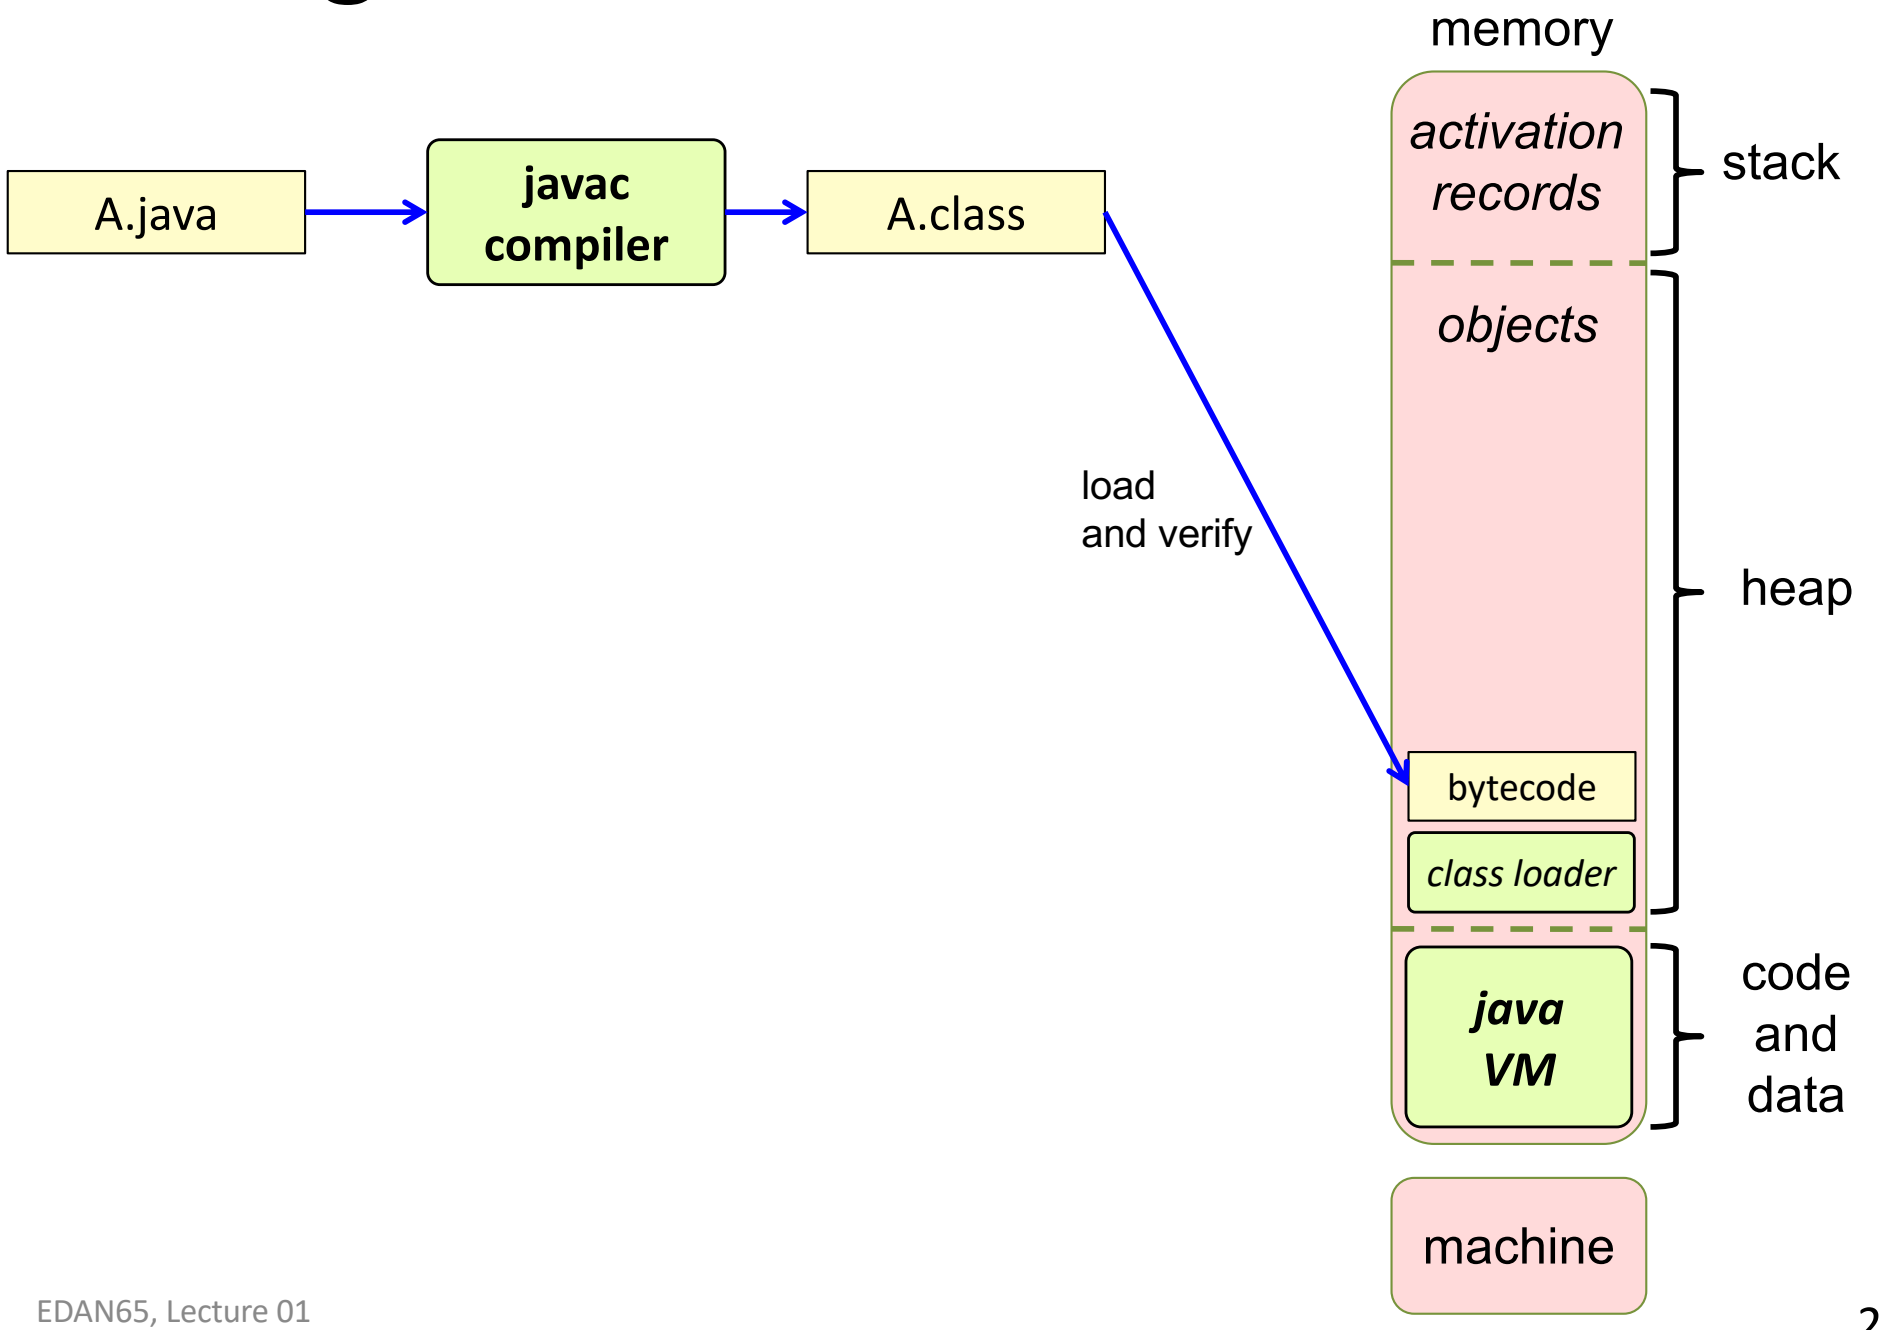


Running Java code?

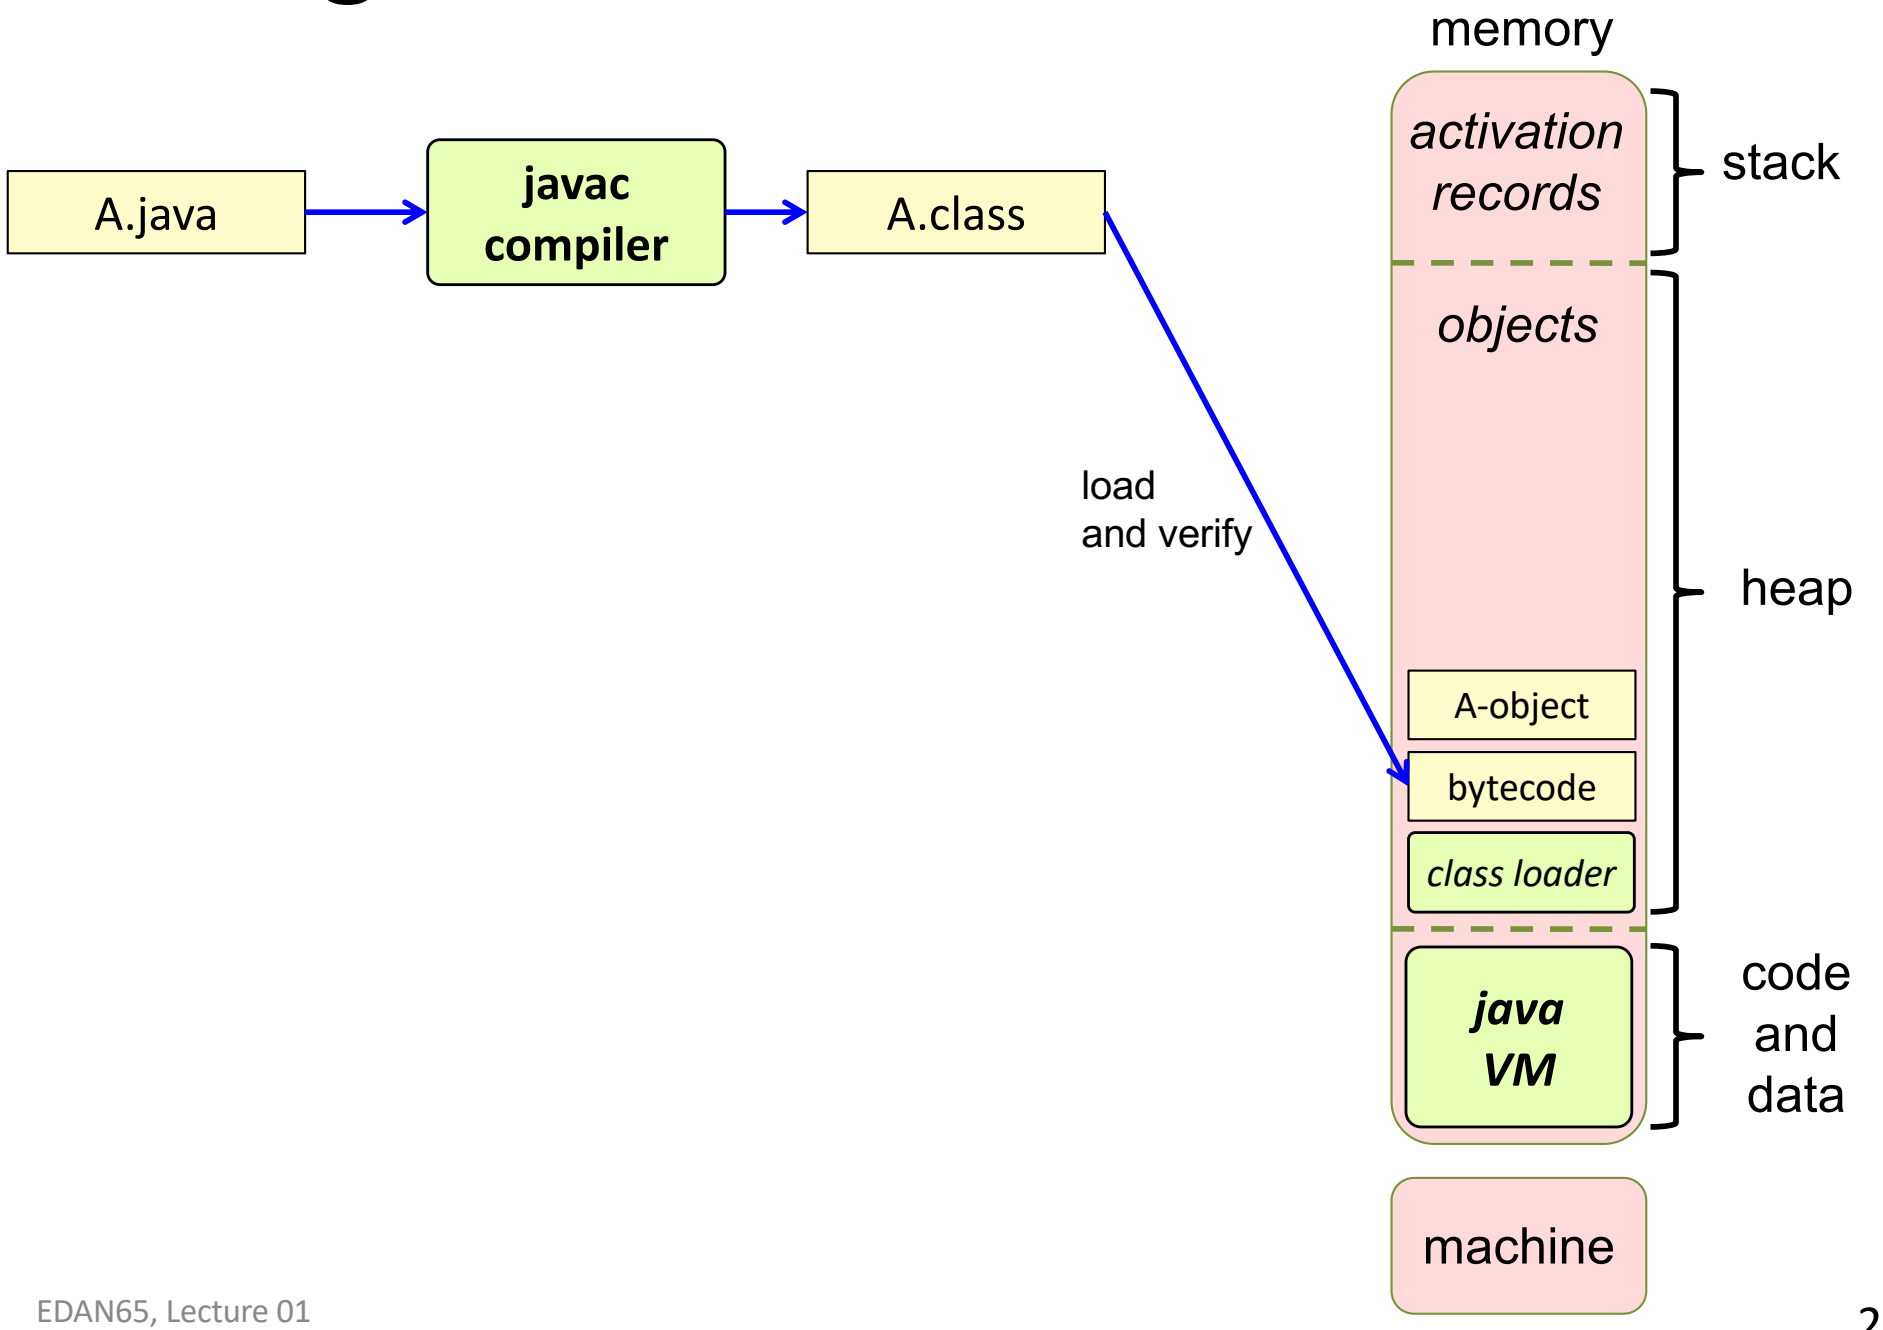




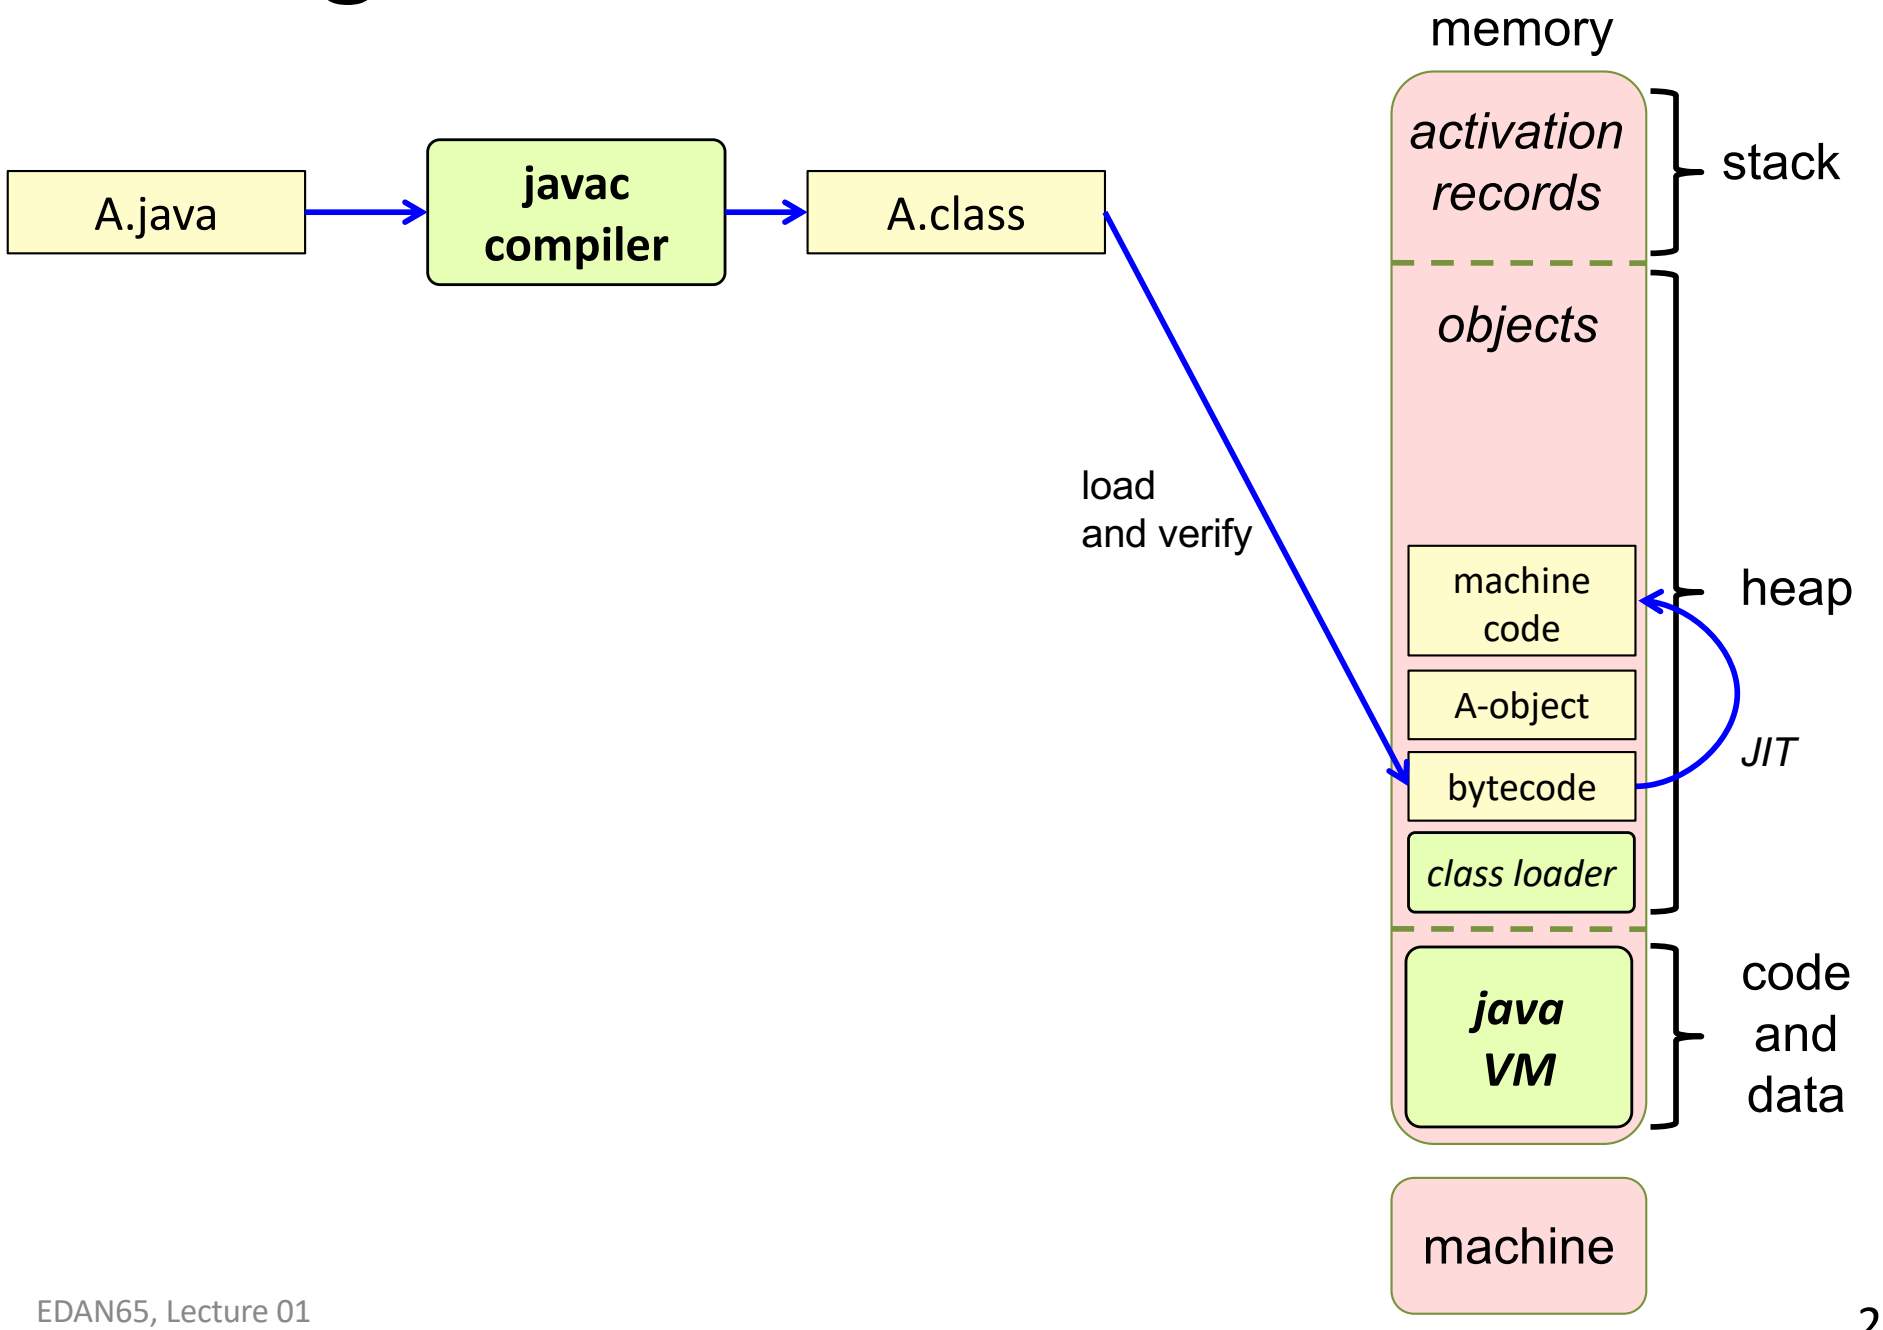
Running Java code?



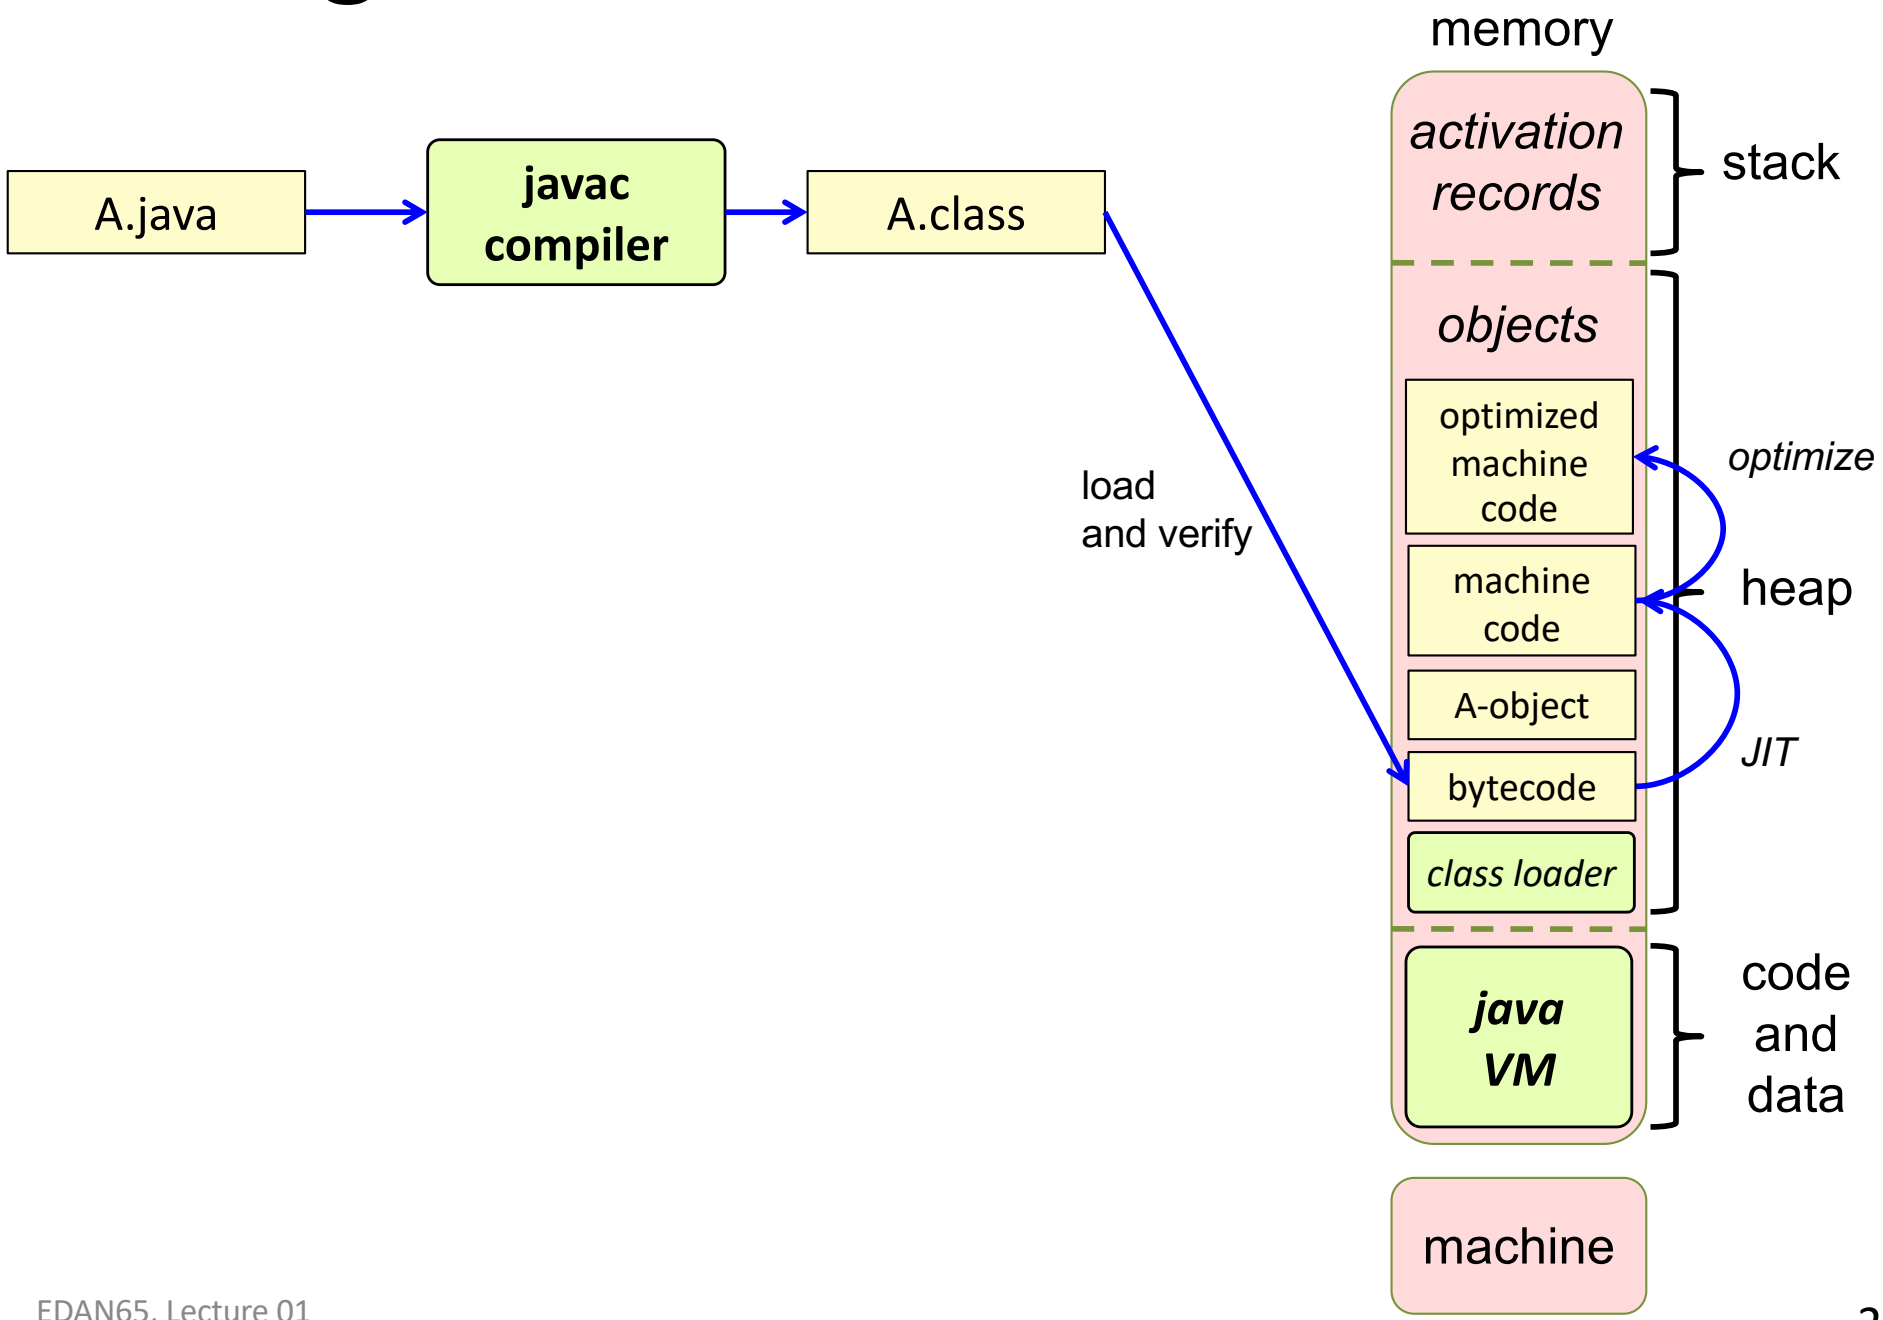
Running Java code?



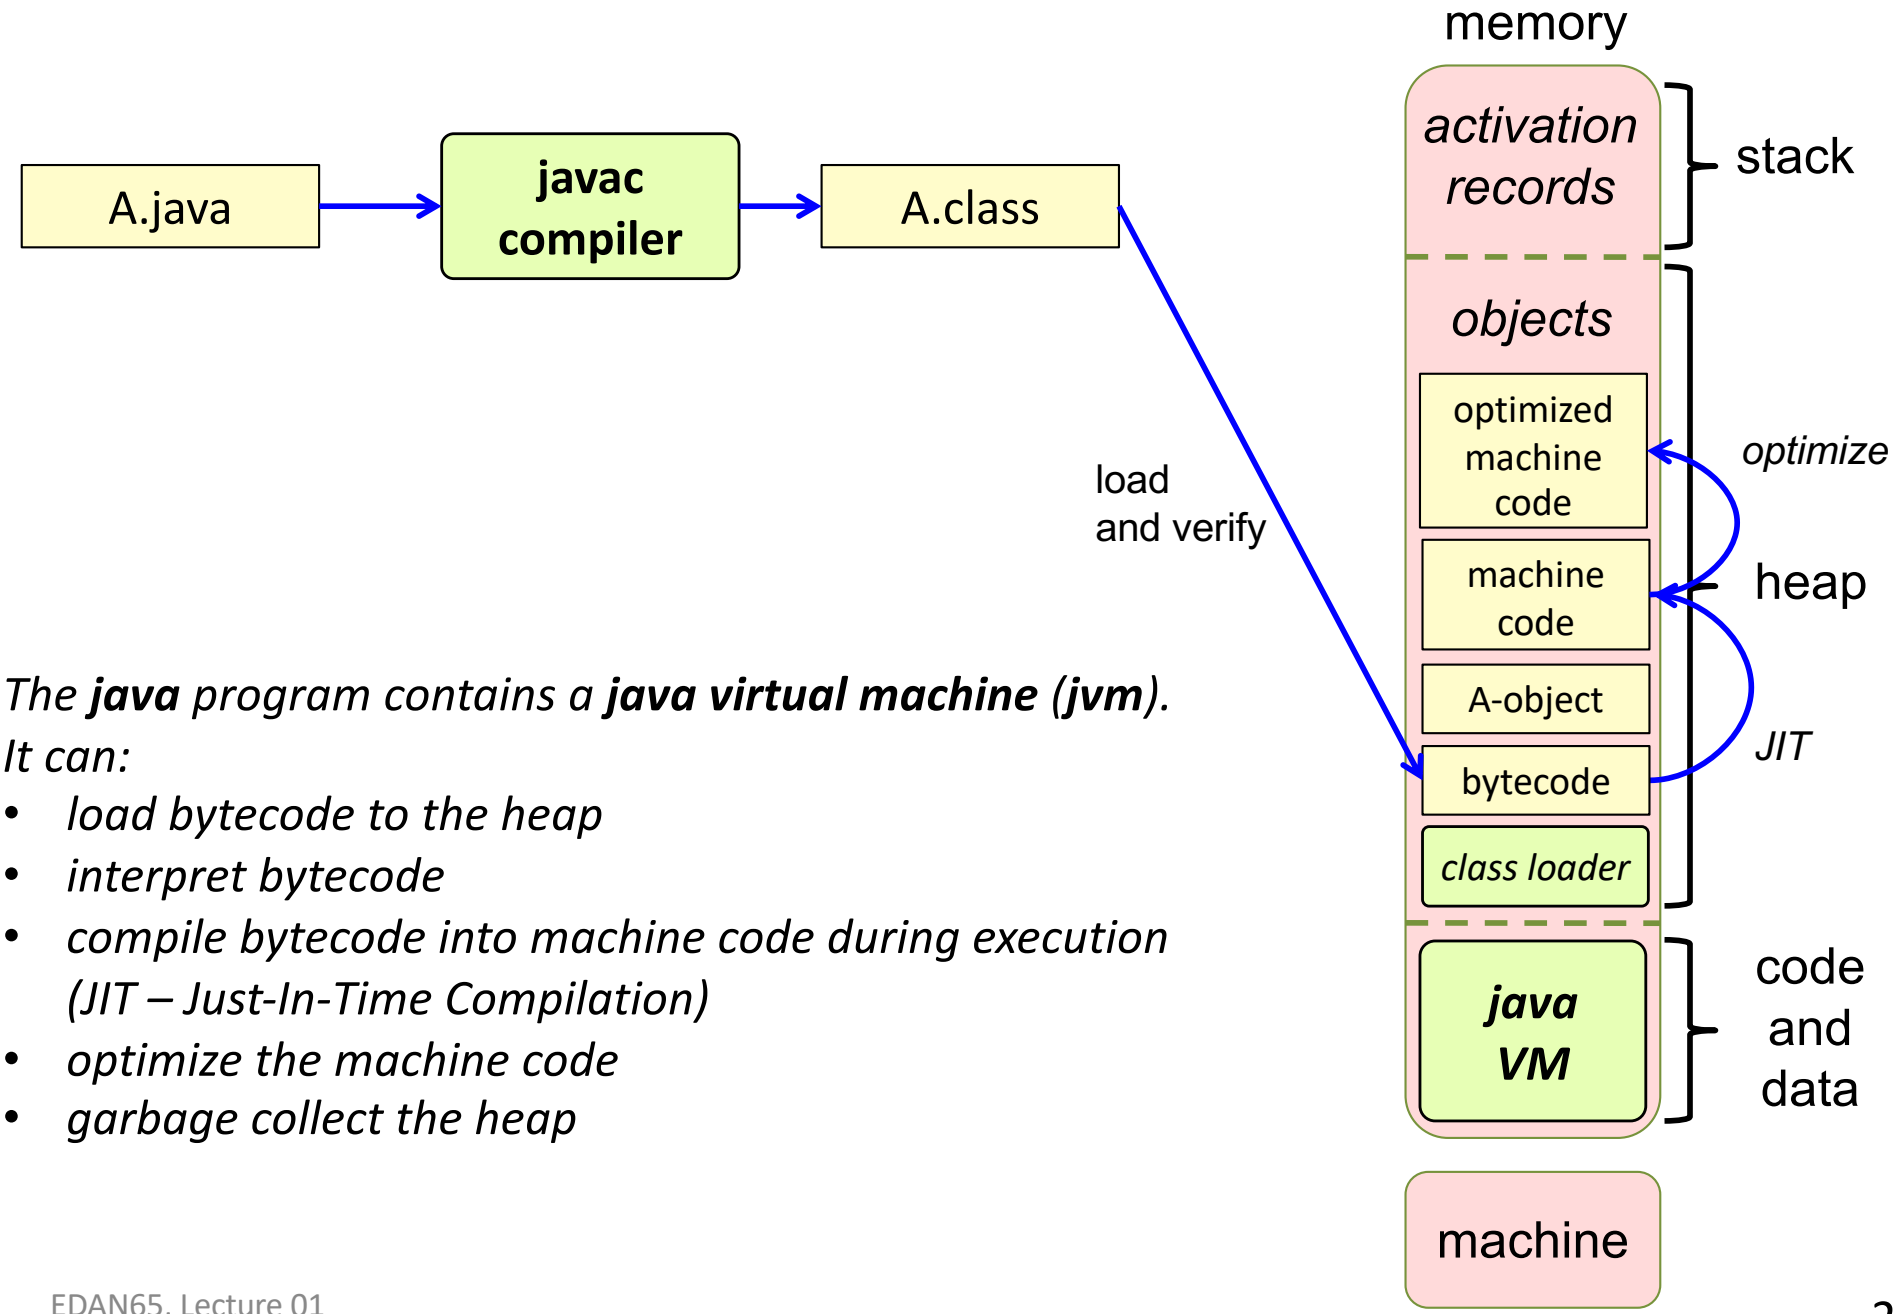
Running Java code?



Running Java code?



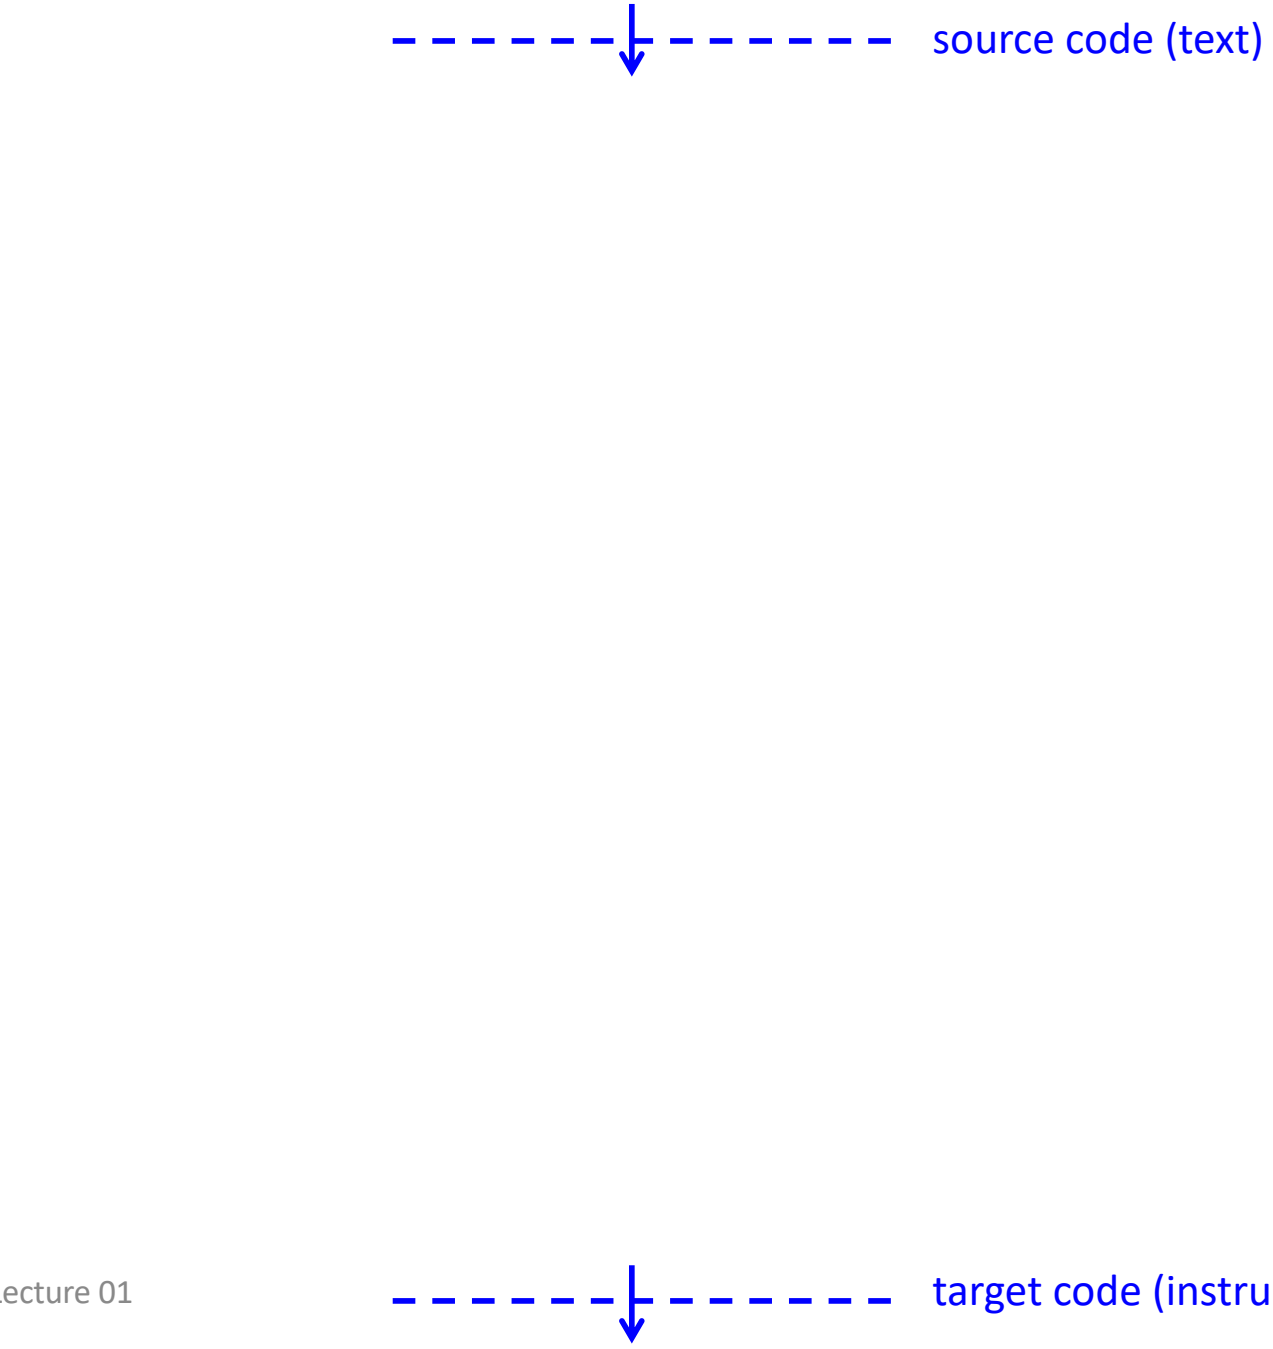
Running Java code?



*The **java** program contains a **java virtual machine** (**jvm**).*
It can:

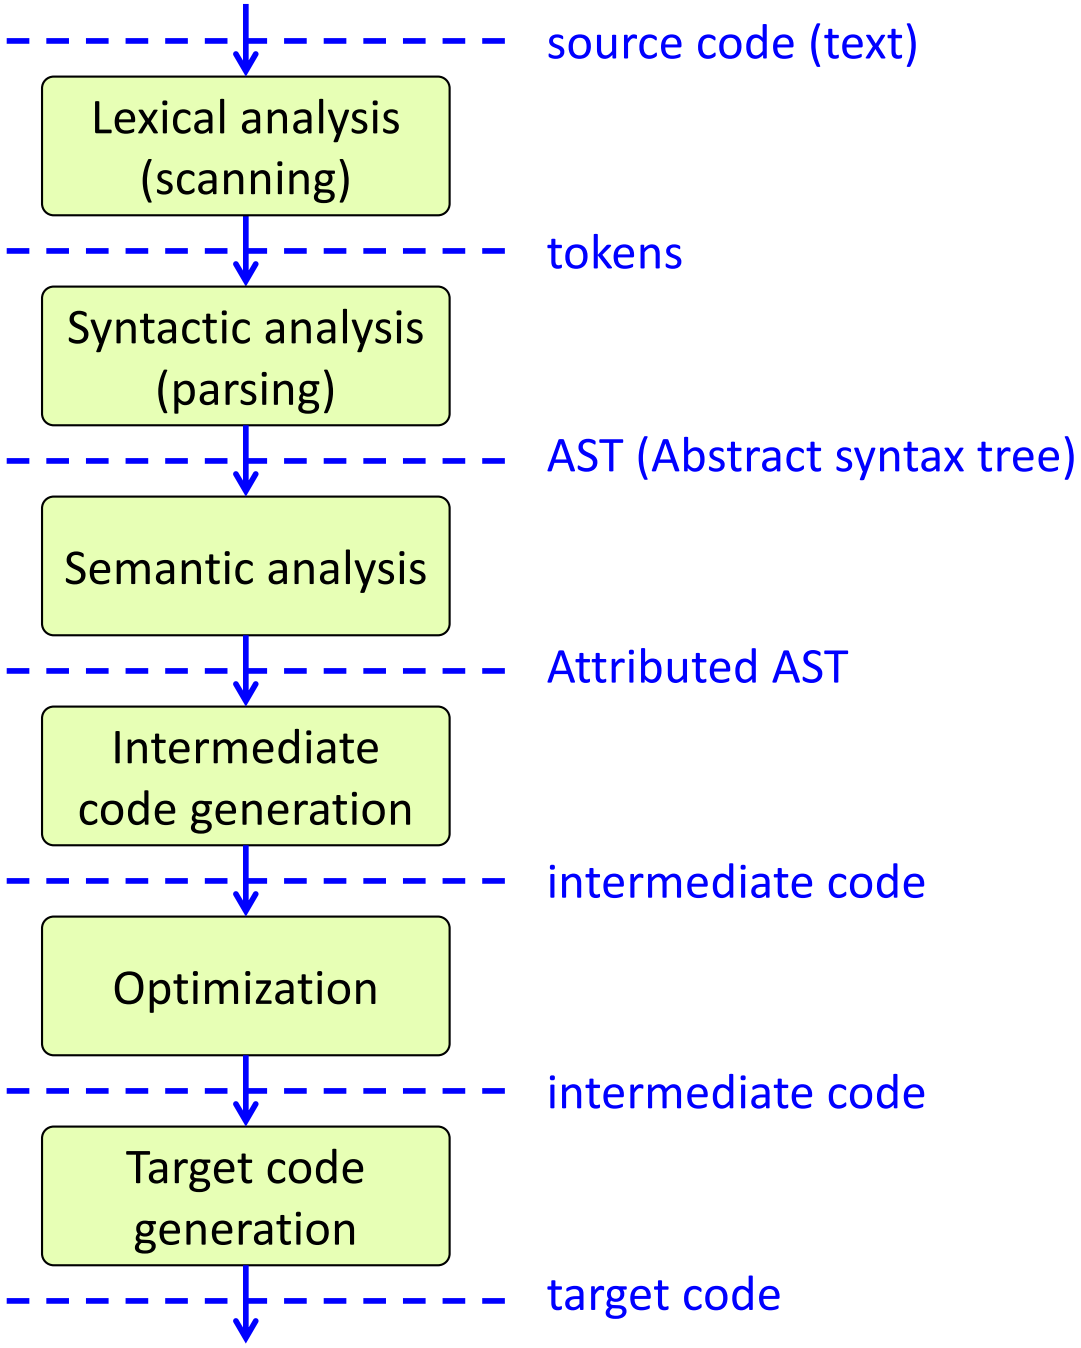
- *load bytecode to the heap*
- *interpret bytecode*
- *compile bytecode into machine code during execution (JIT – Just-In-Time Compilation)*
- *optimize the machine code*
- *garbage collect the heap*

Inside the compiler:



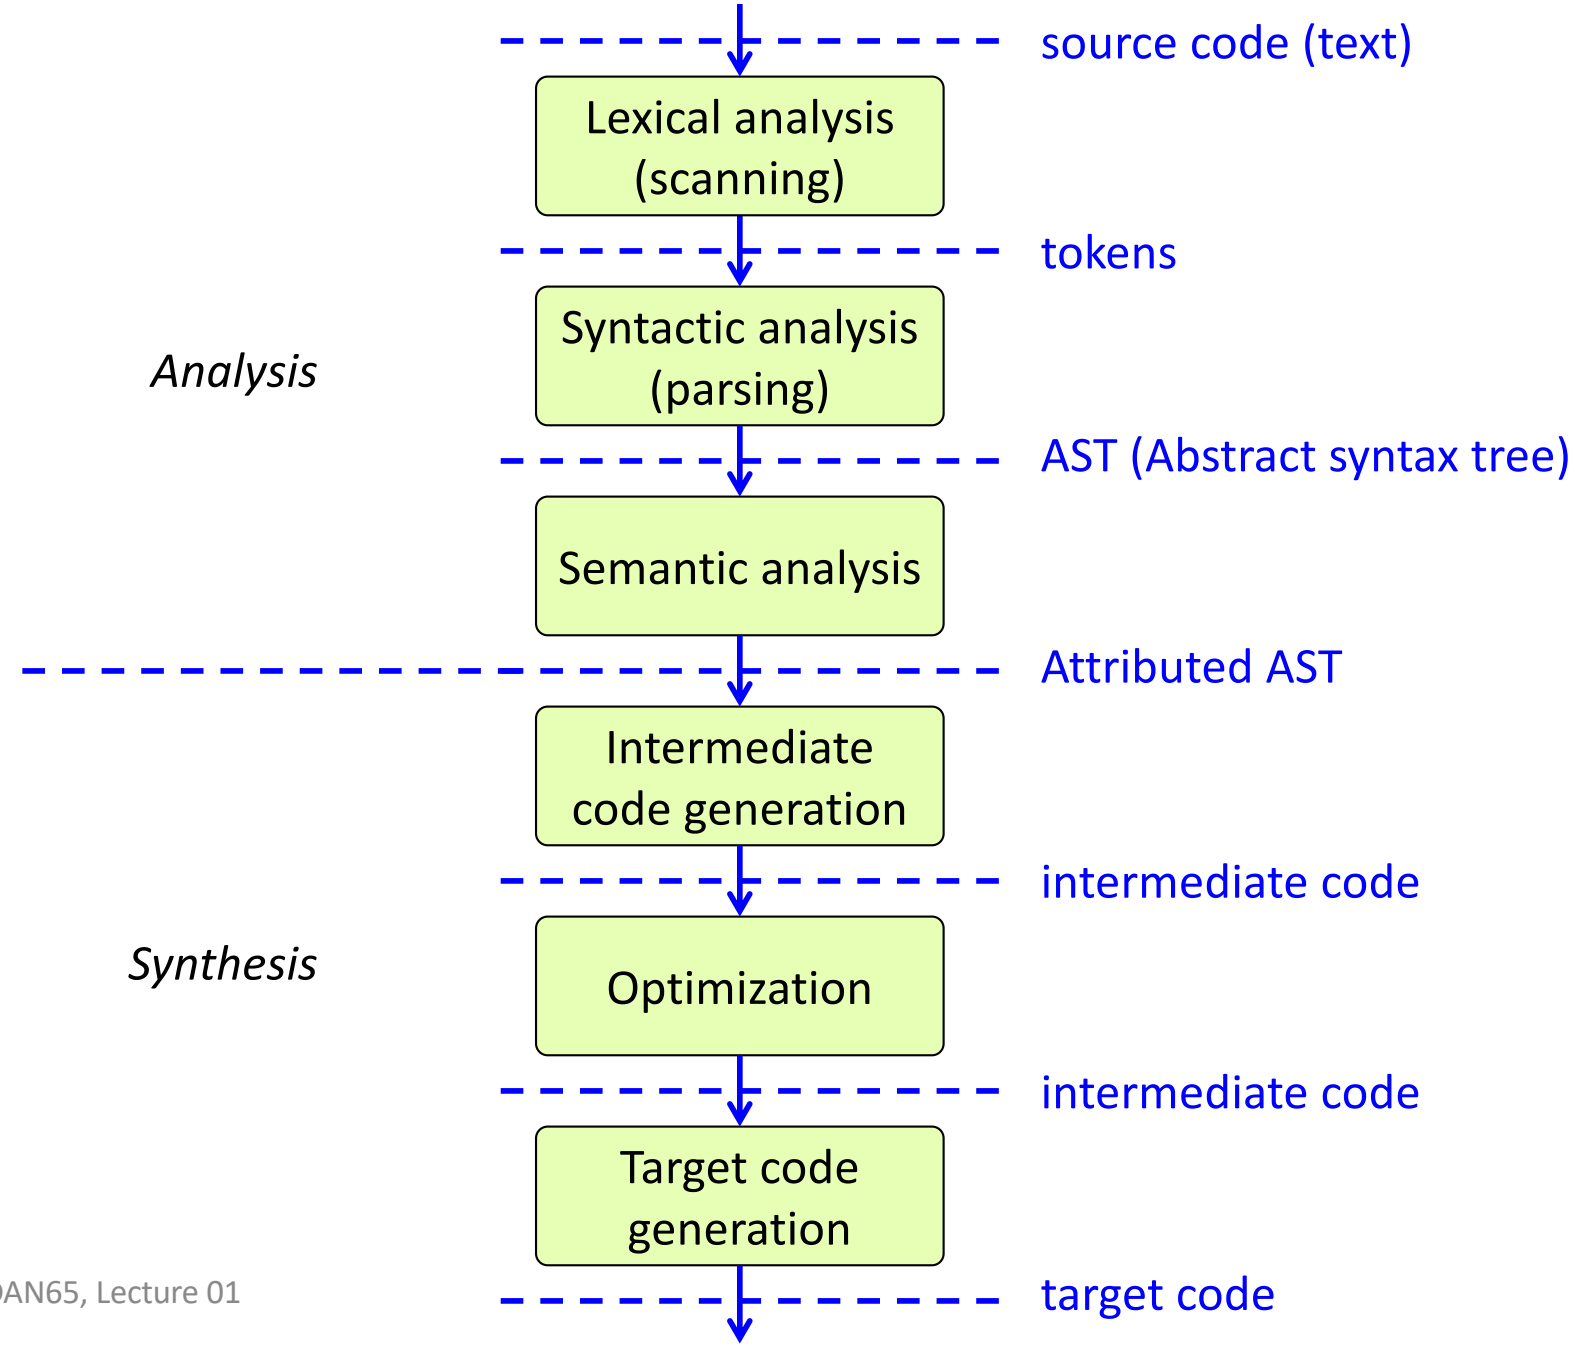
Inside the compiler:

Each ***phase*** converts the program from one ***representation*** to another

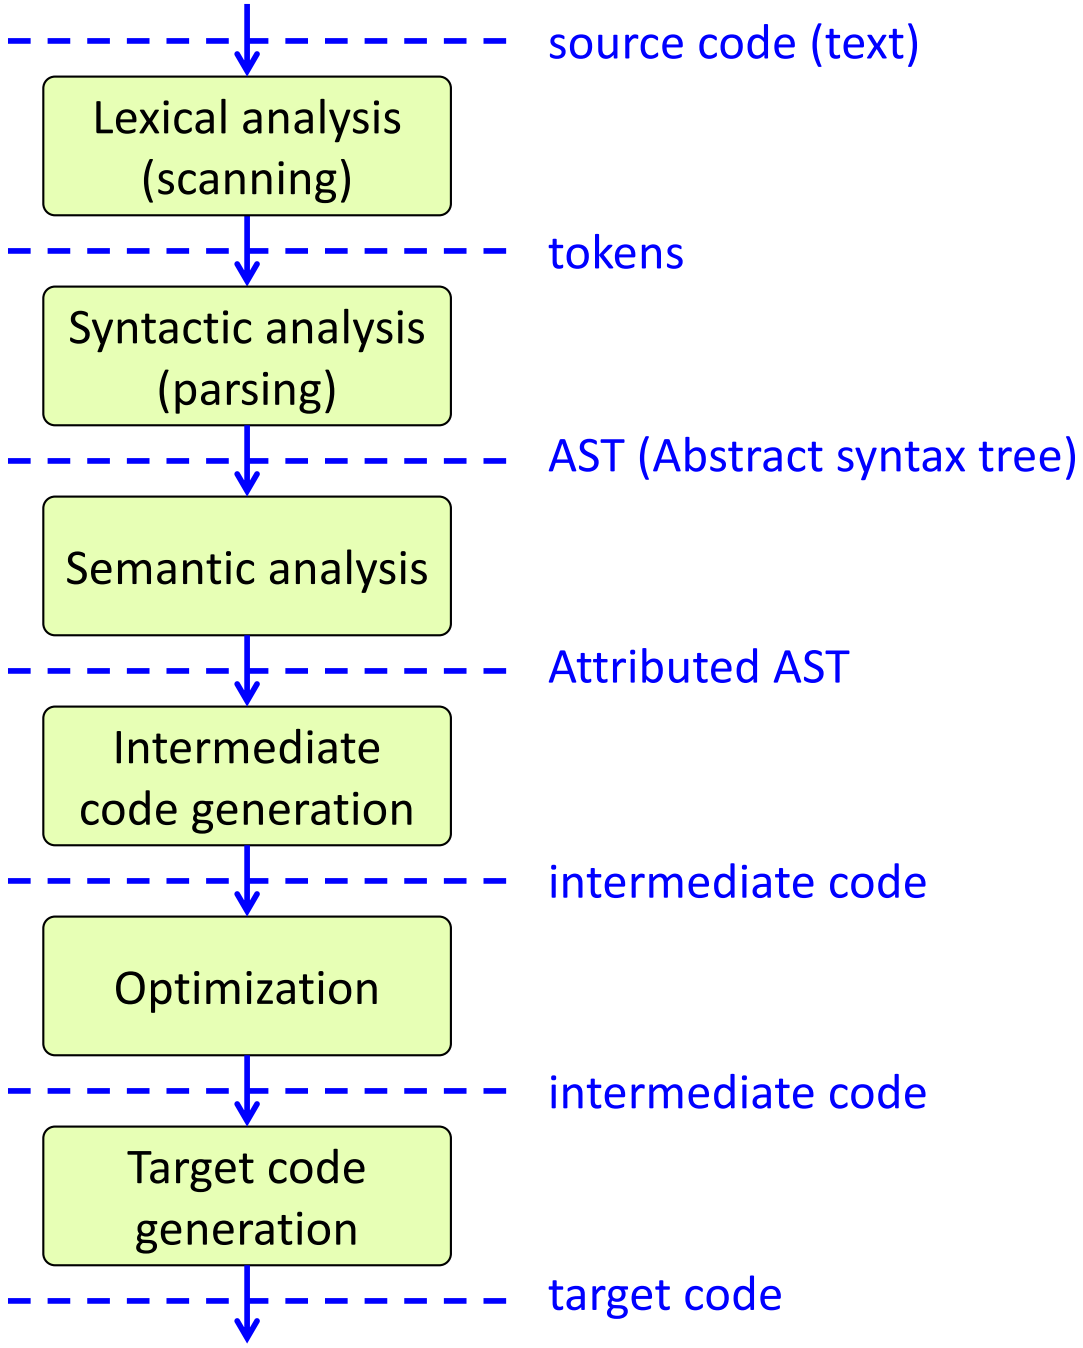


Inside the compiler:

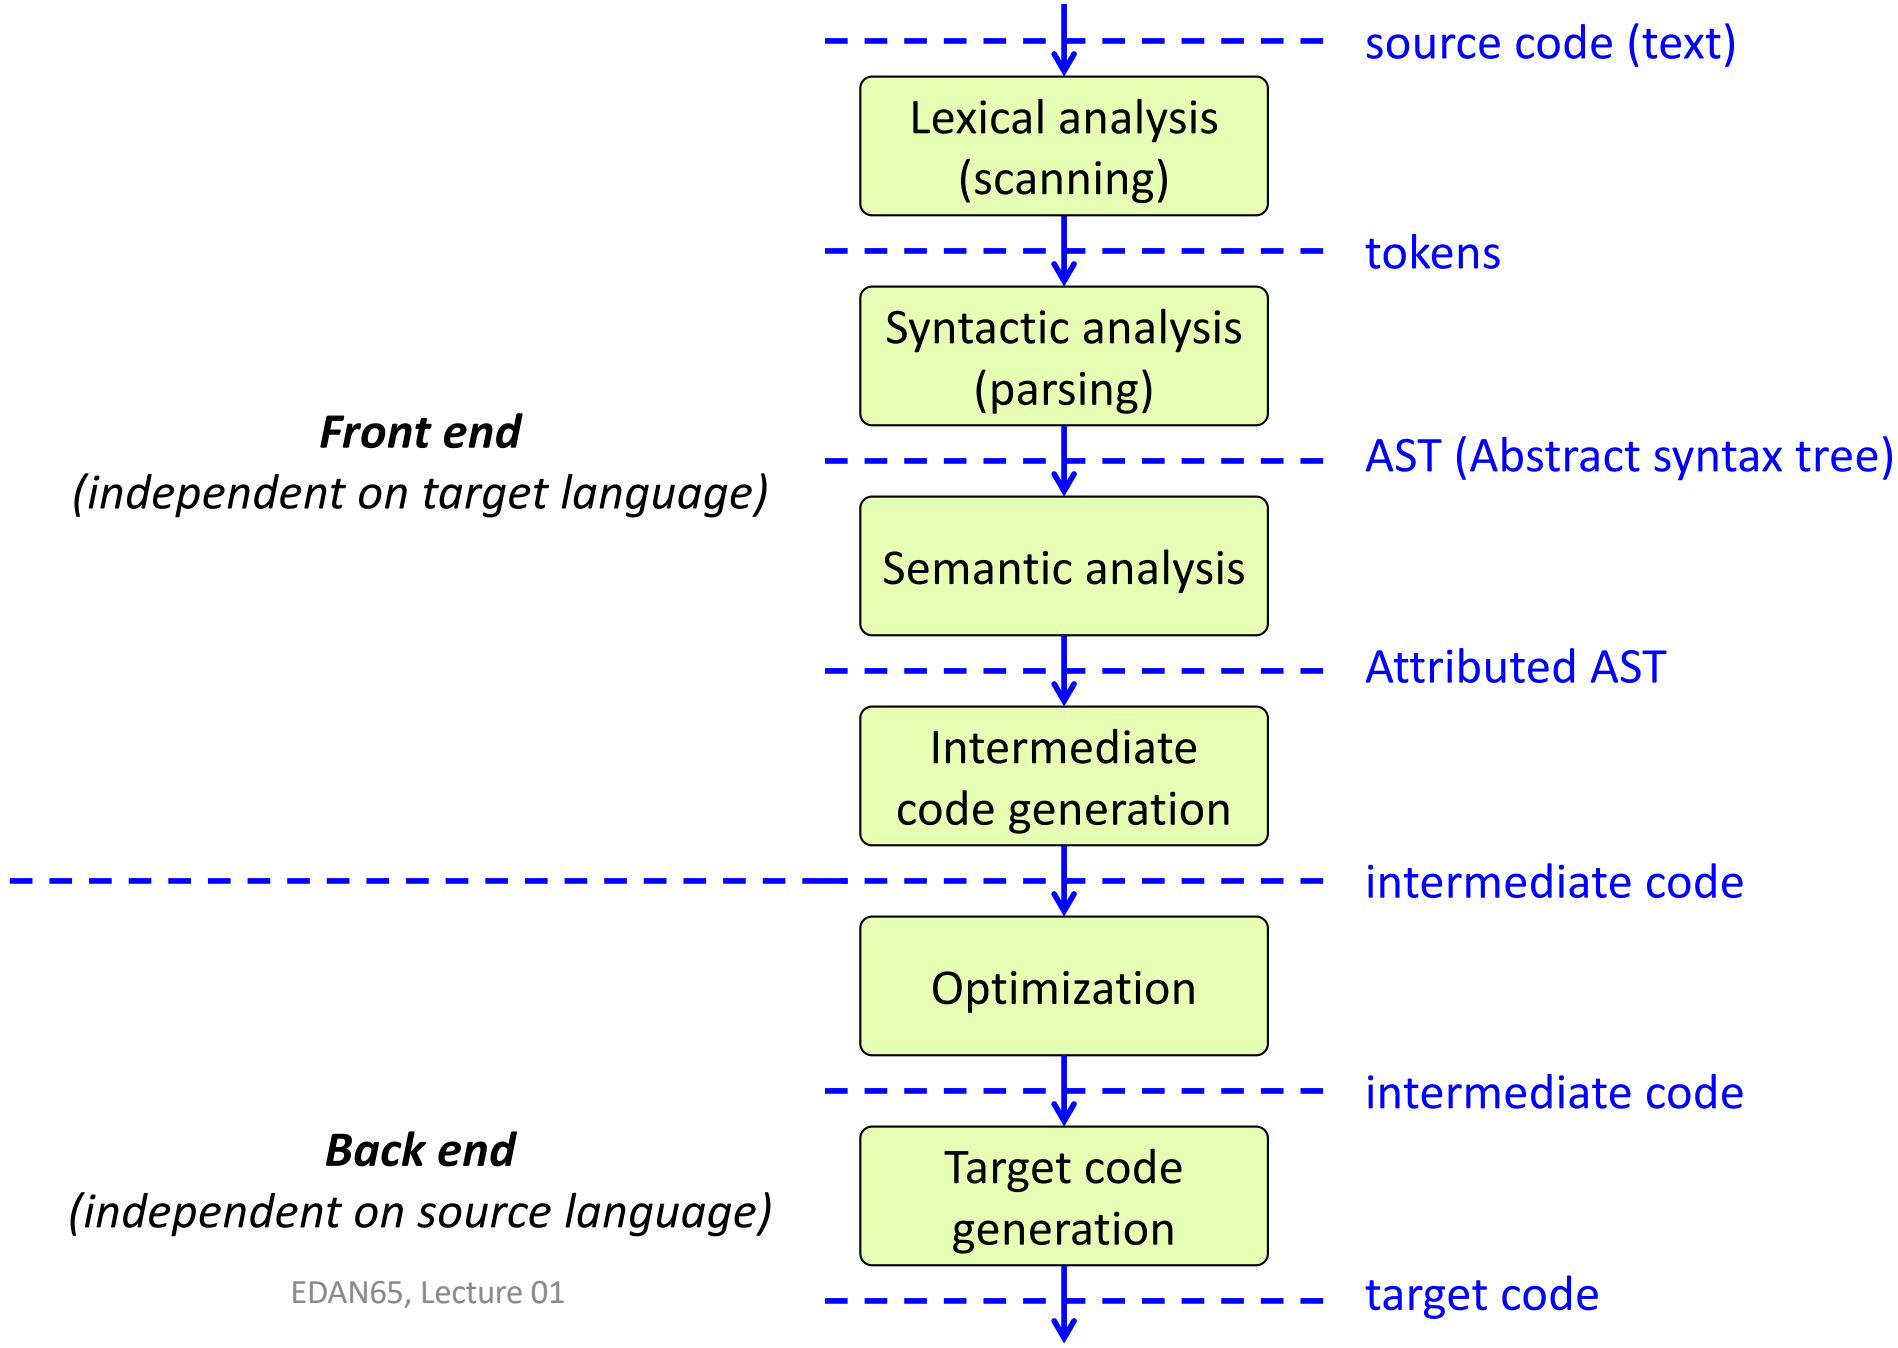
Each ***phase*** converts the program from one ***representation*** to another



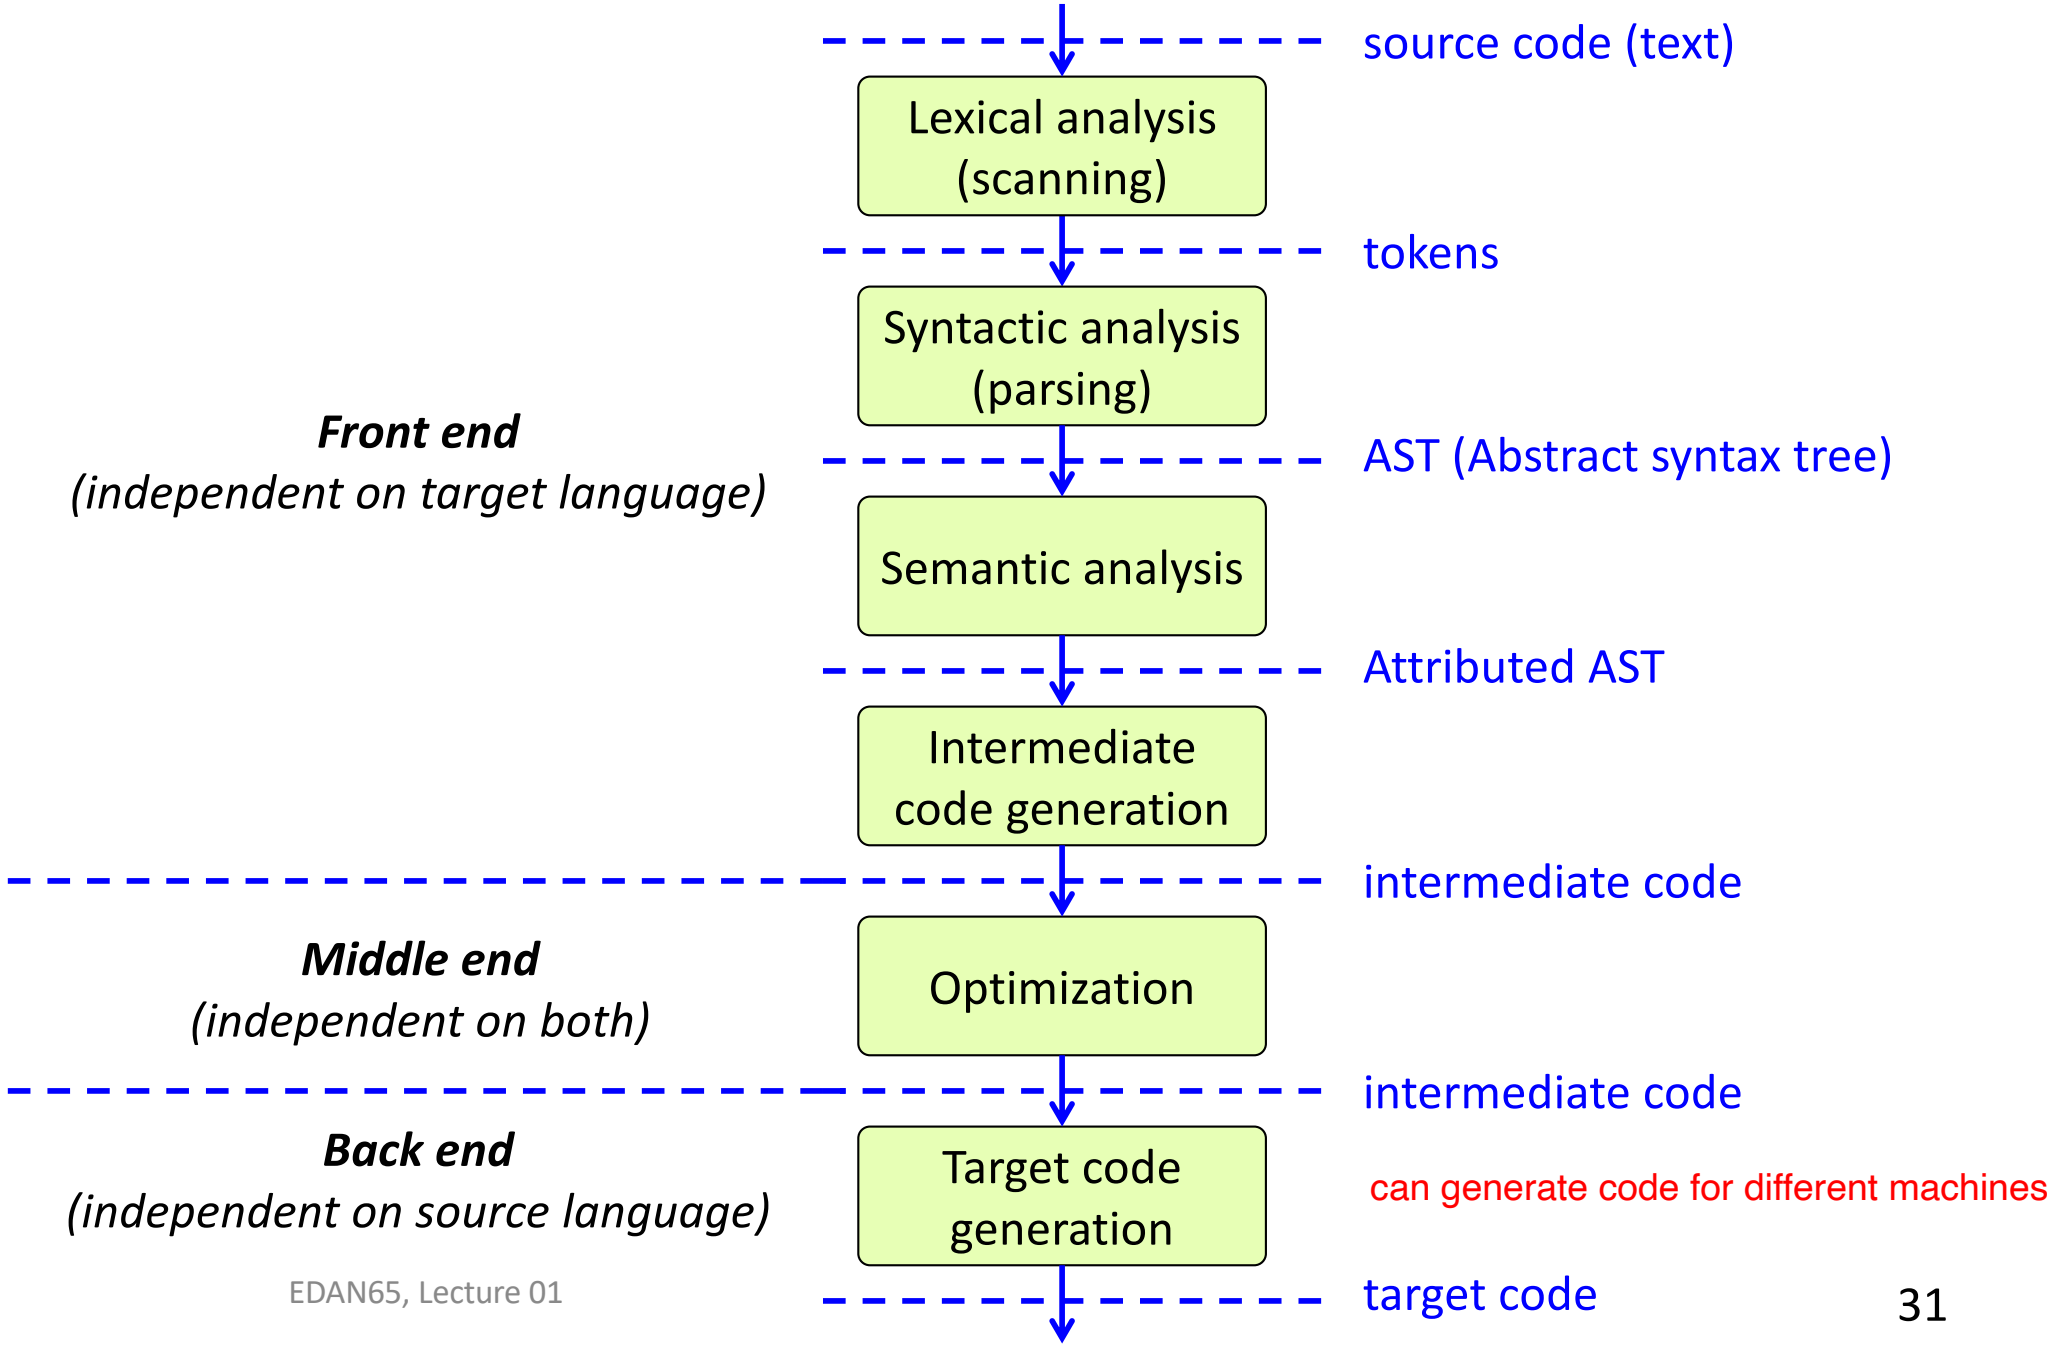
Front and back end:



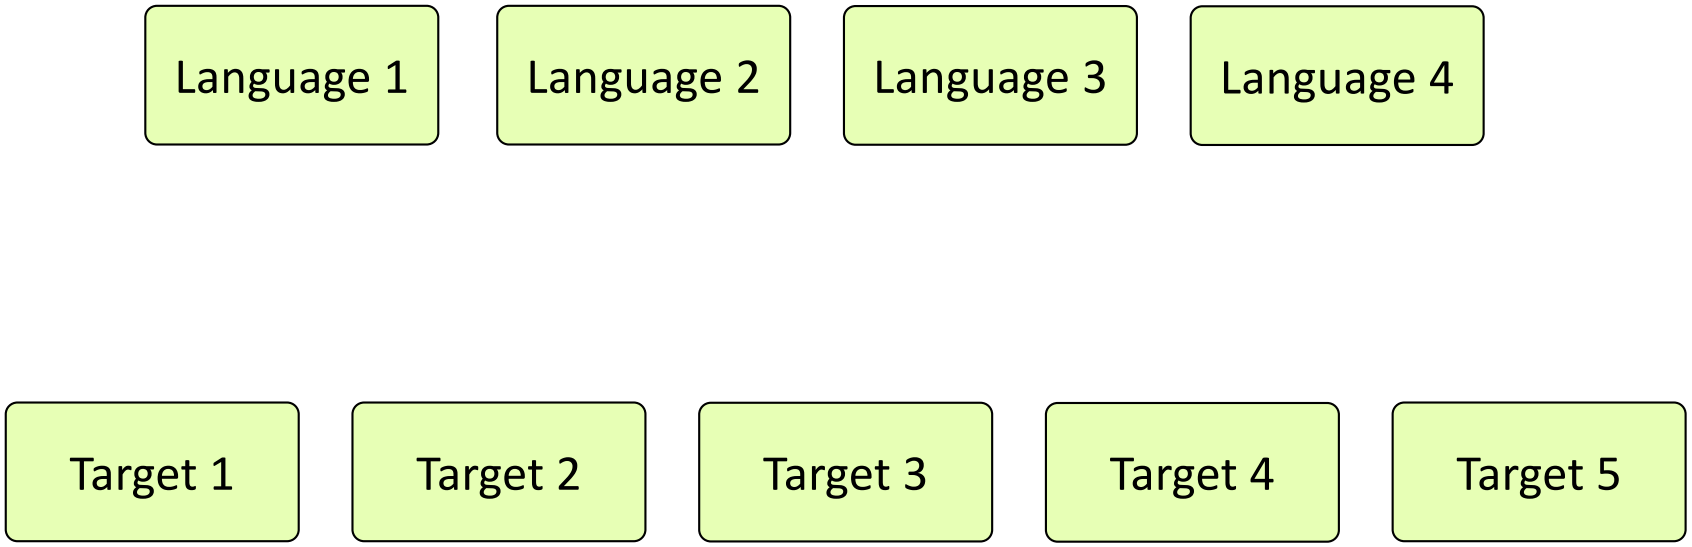
Front and back end:



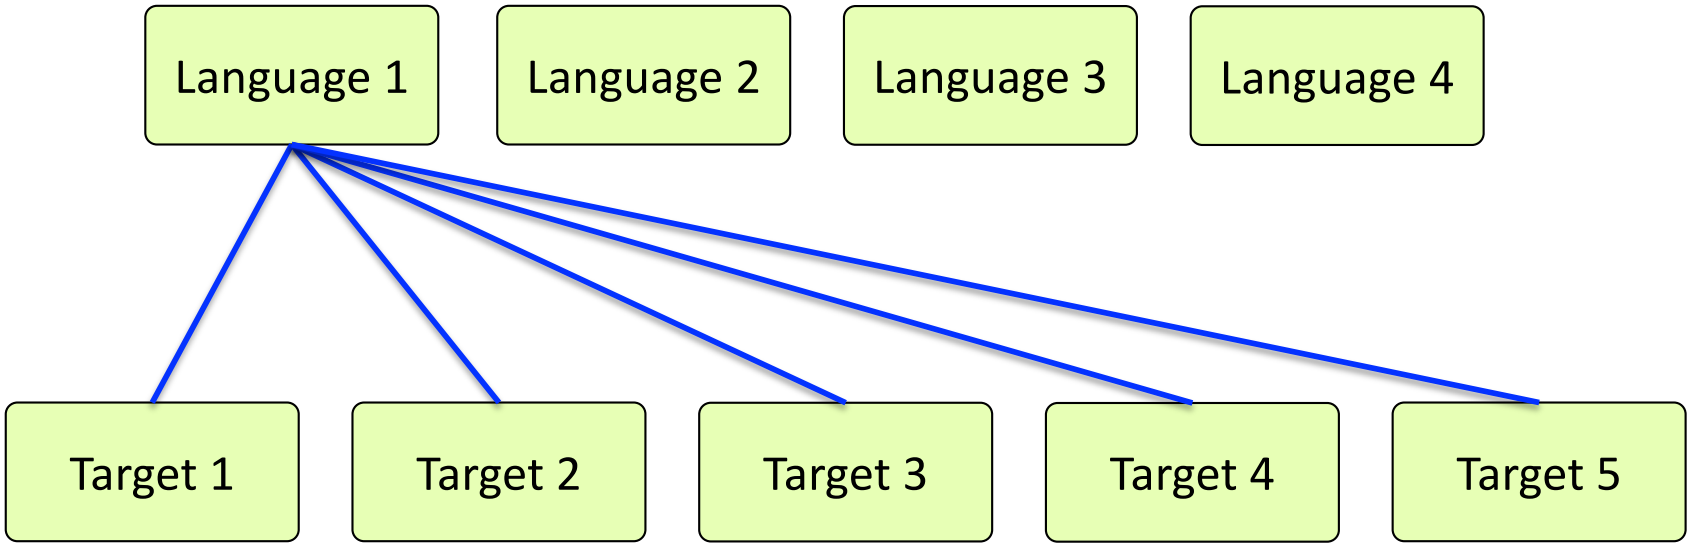
Front and back end:



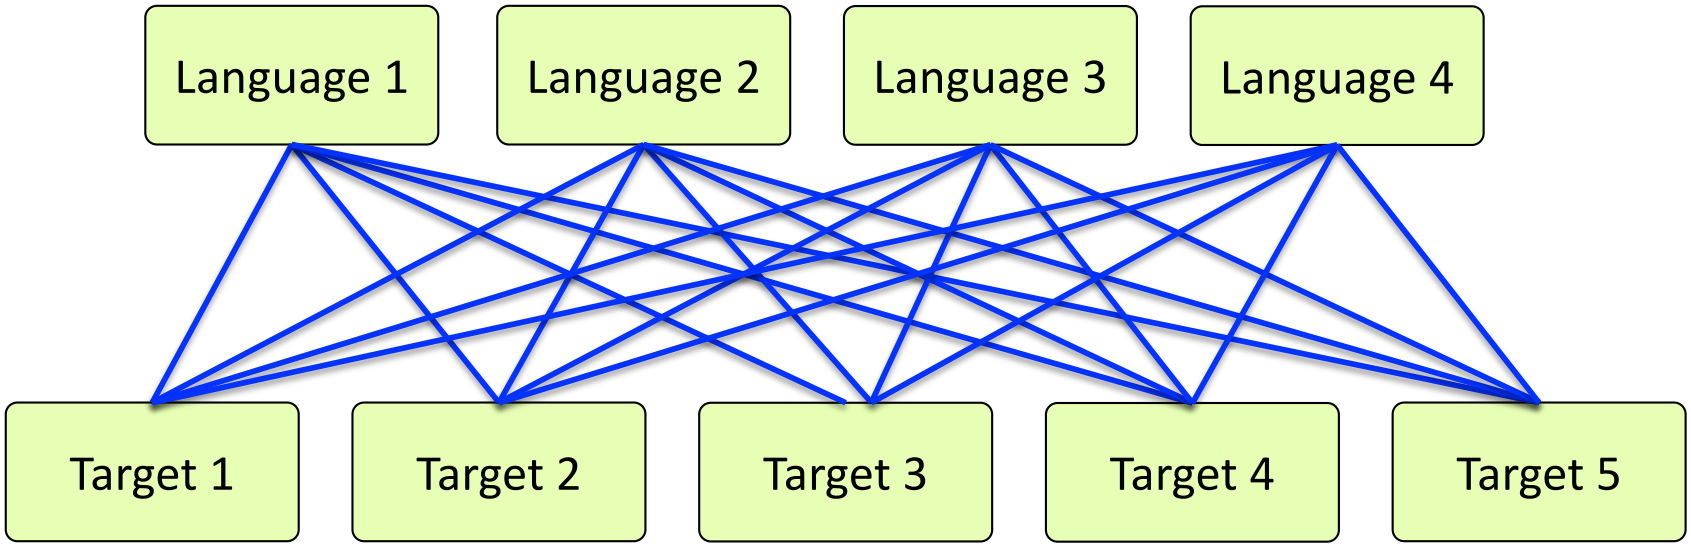
Multiple languages and target machines



Multiple languages and target machines



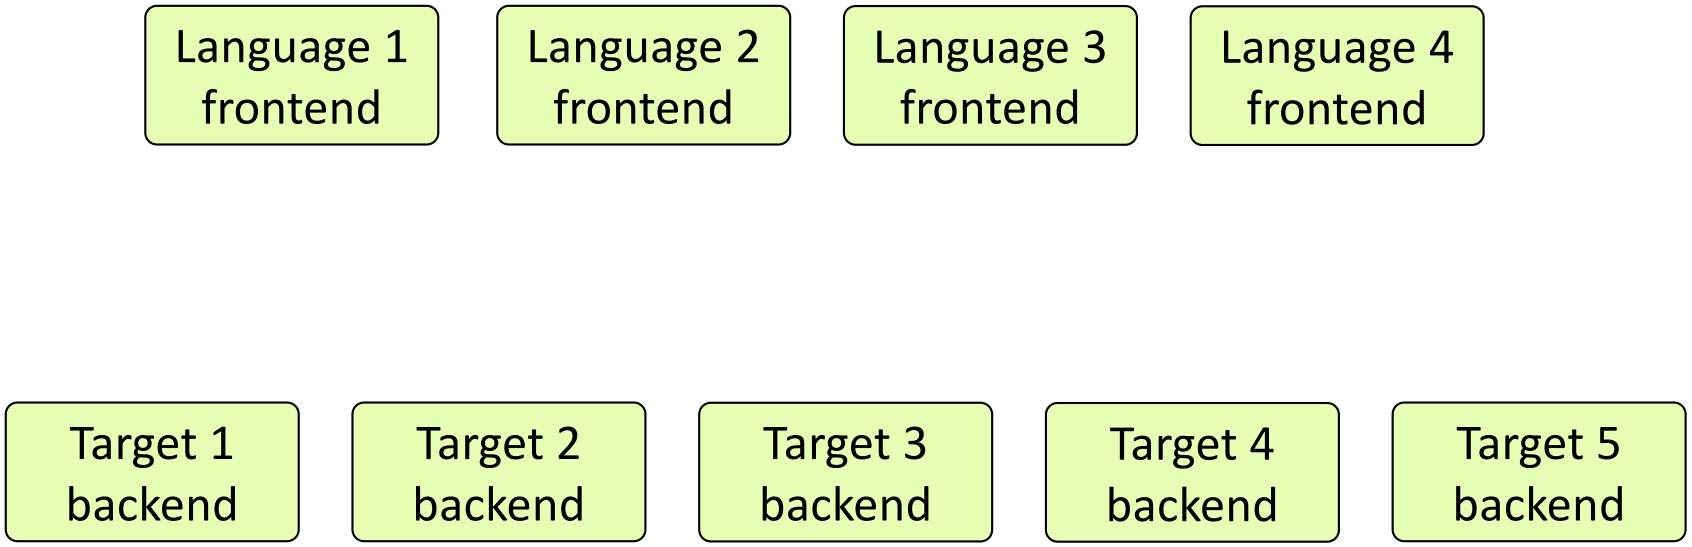
Multiple languages and target machines



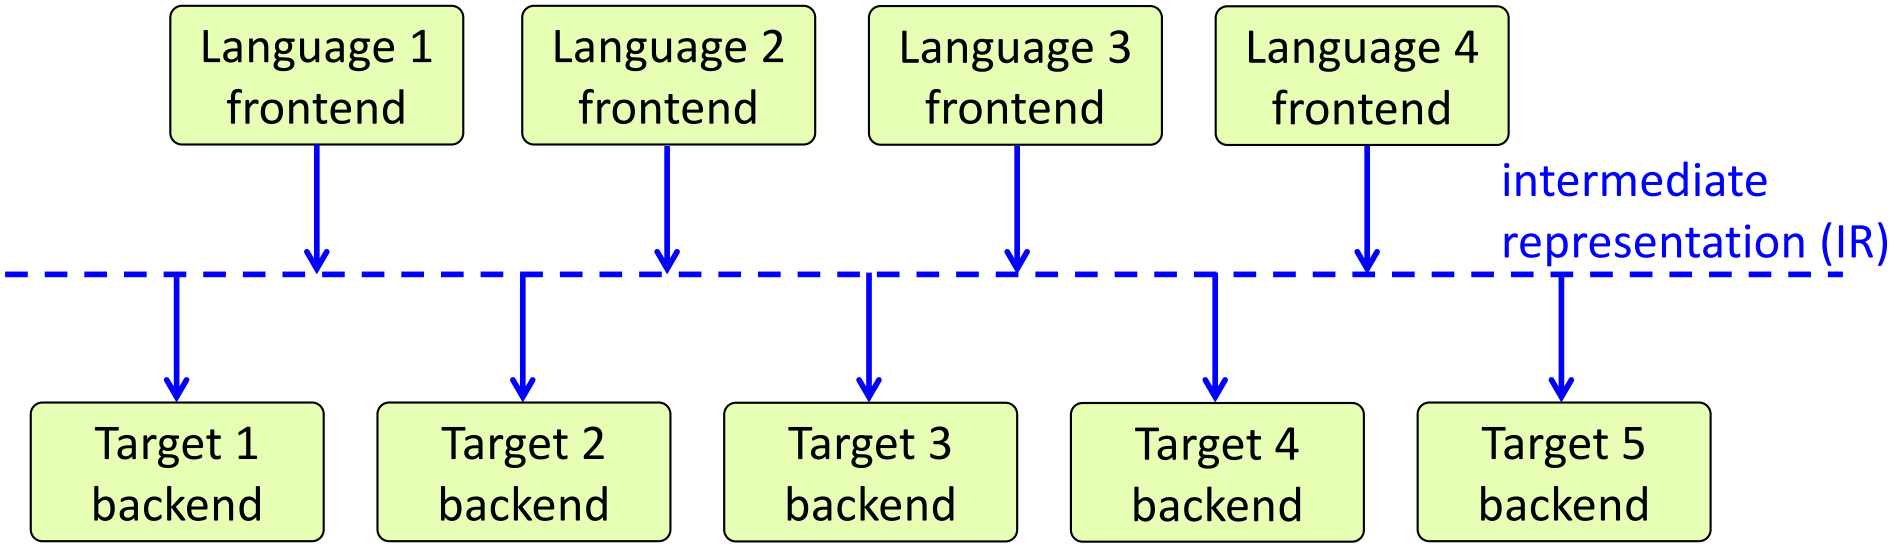
m languages
n target machines
m*n compilers

Is there a smarter way?

Multiple languages and target machines

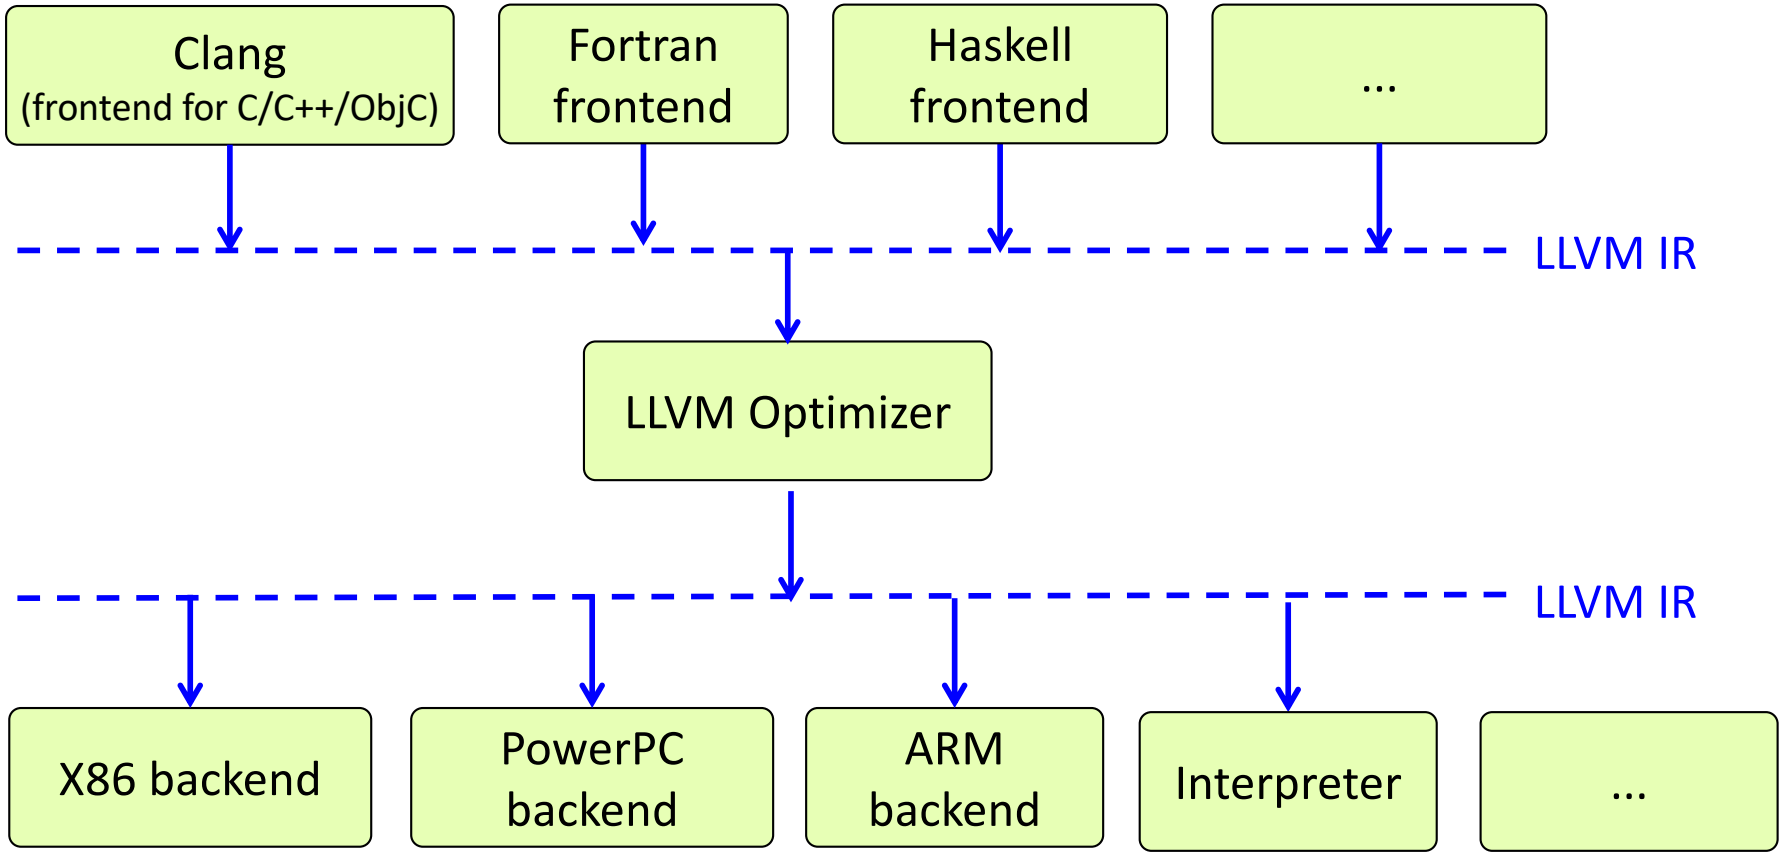


Multiple languages and target machines

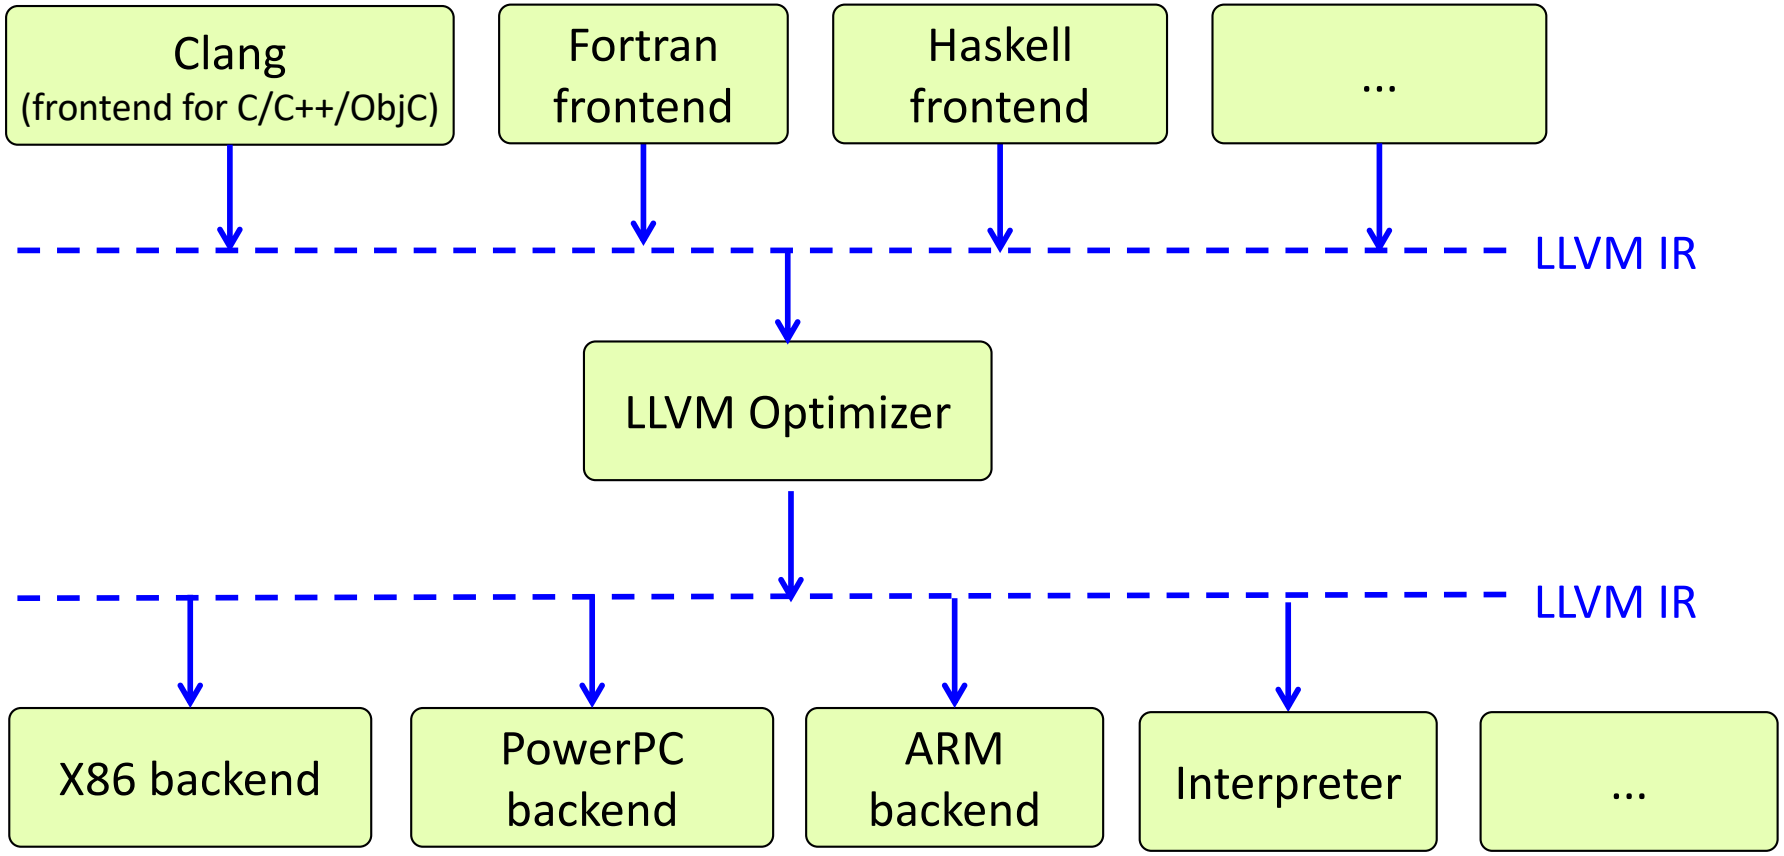


m language frontends
n target backends
m + n components

LLVM example



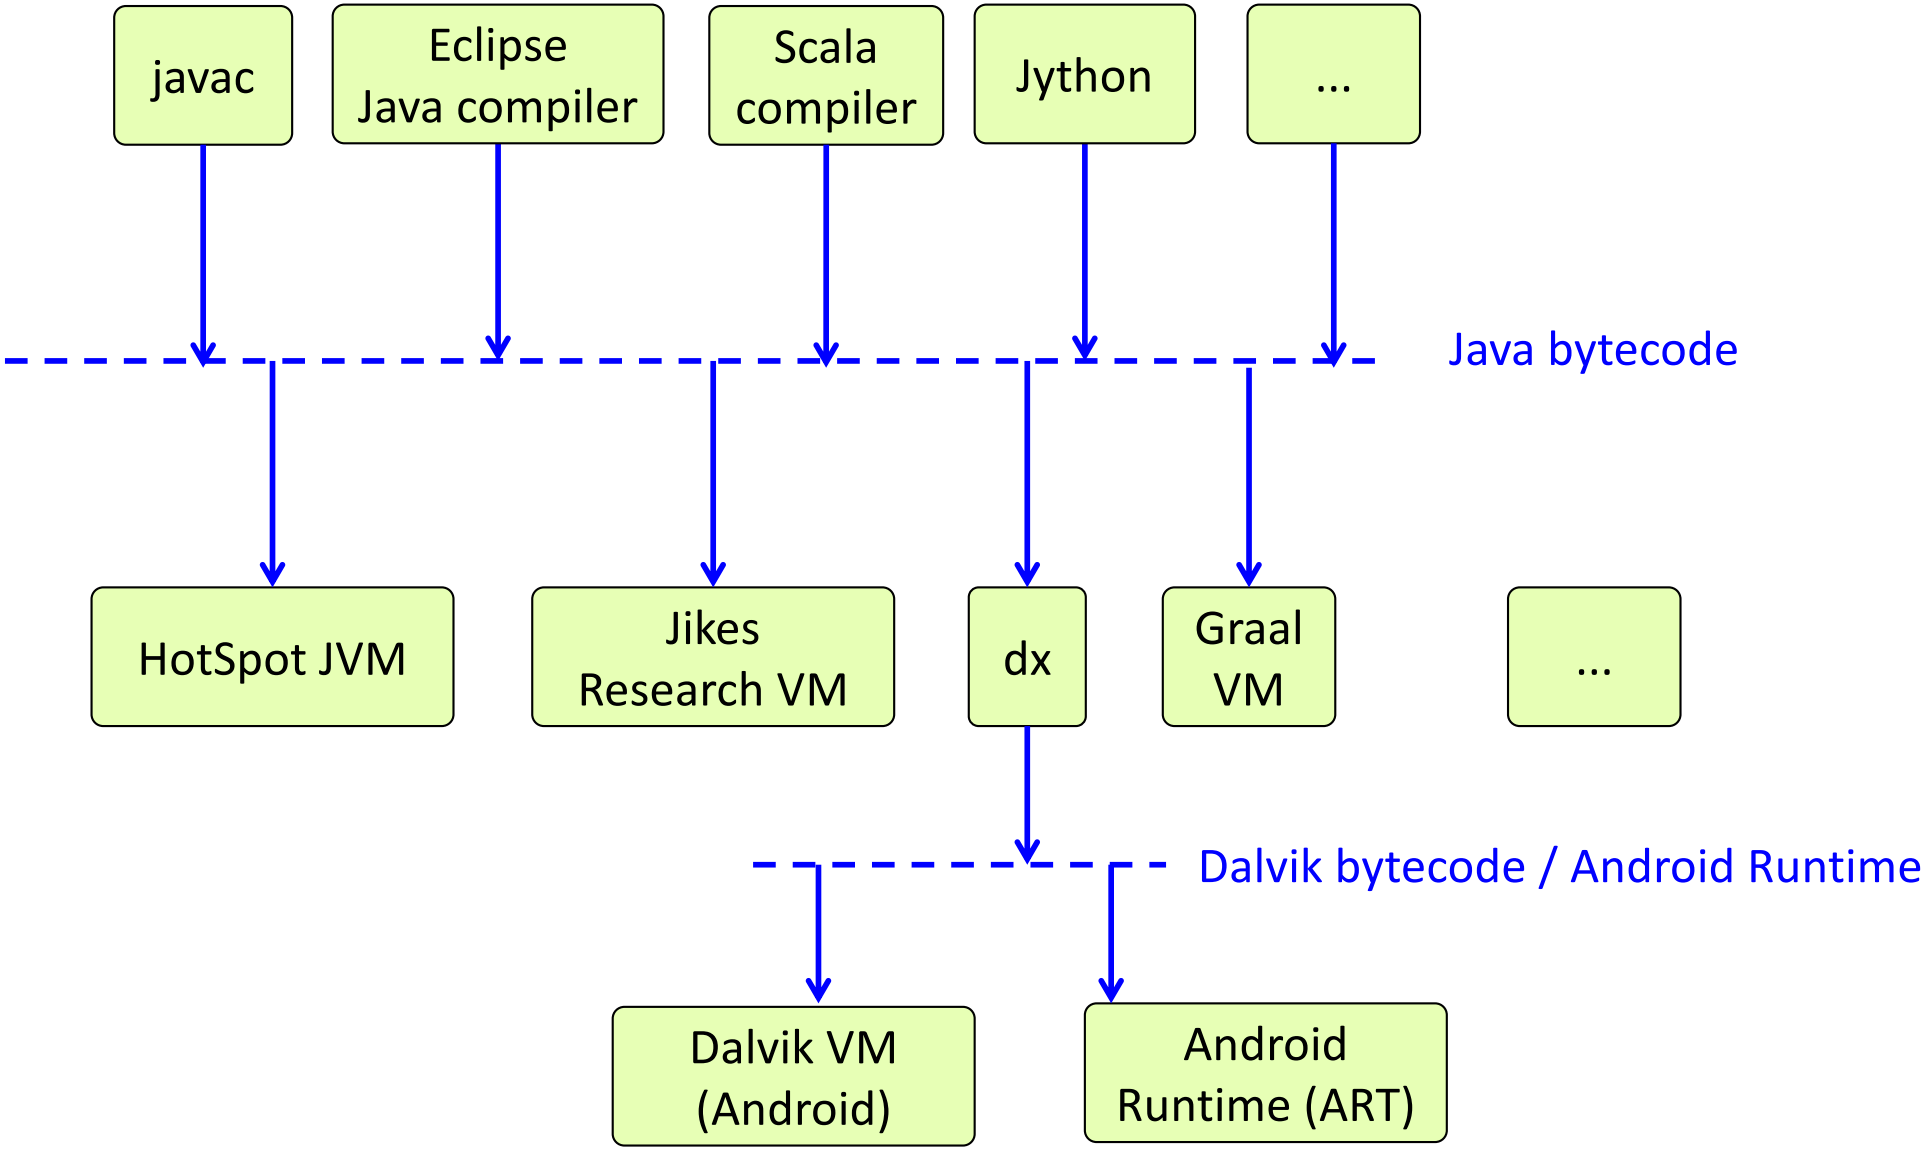
LLVM example



Why?

- Implement m front ends + n back ends instead of m * n compilers.
- Many optimizations are best performed on intermediate code.
- Easier to debug the front end using an interpreter than a target machine

Java example:



Some terminology

- A ***compiler*** translates code in a high-level language to a lower-level language.
  Examples: Compiling Java source code to Java bytecode. Compiling C source code to assembly code.

- An ***interpreter*** is software that executes a high/low level program, often by calling one procedure for each program construct. (This is in contrast to executing the program directly on hardware.)
  Example: A Python interpreter reads Python code and runs it.

- A ***transpiler*** (or source-to-source translator) translates code from one high-level language to another.
  Example: Transpiling Typescript source code to Javascript.

- A ***virtual machine (VM)*** is an interpreter that executes low-level, usually platform-independent code. (This is in the context of language implementation. In other contexts, the term "virtual machine" can mean operating system virtualization.)
  Example: The JVM (Java Virtual Machine) executes Java bytecode.

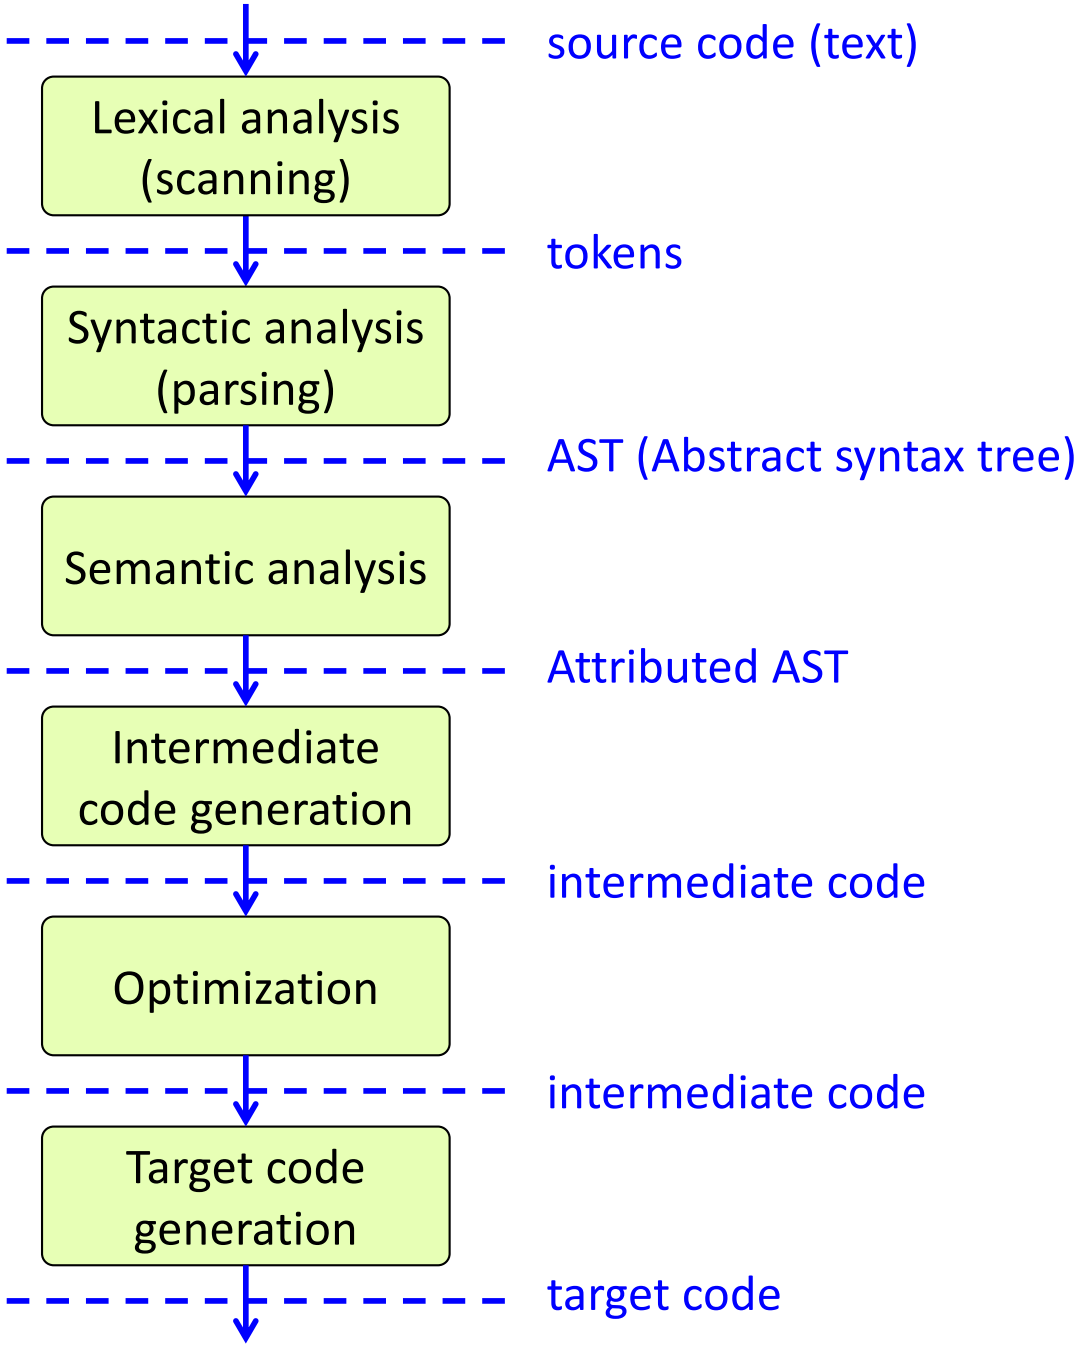
- Platform-independent low-level code, designed to be executed by a VM, was originally called ***p-code*** (portable code), but is now usually called ***bytecode***.

- An interpreter or VM may use a ***JIT*** ("Just In Time") compiler to compile all or parts of the program into machine code during execution. In contrast, a traditional compiler compiles to machine code ***AOT*** ("Ahead Of Time"), i.e., before execution starts.

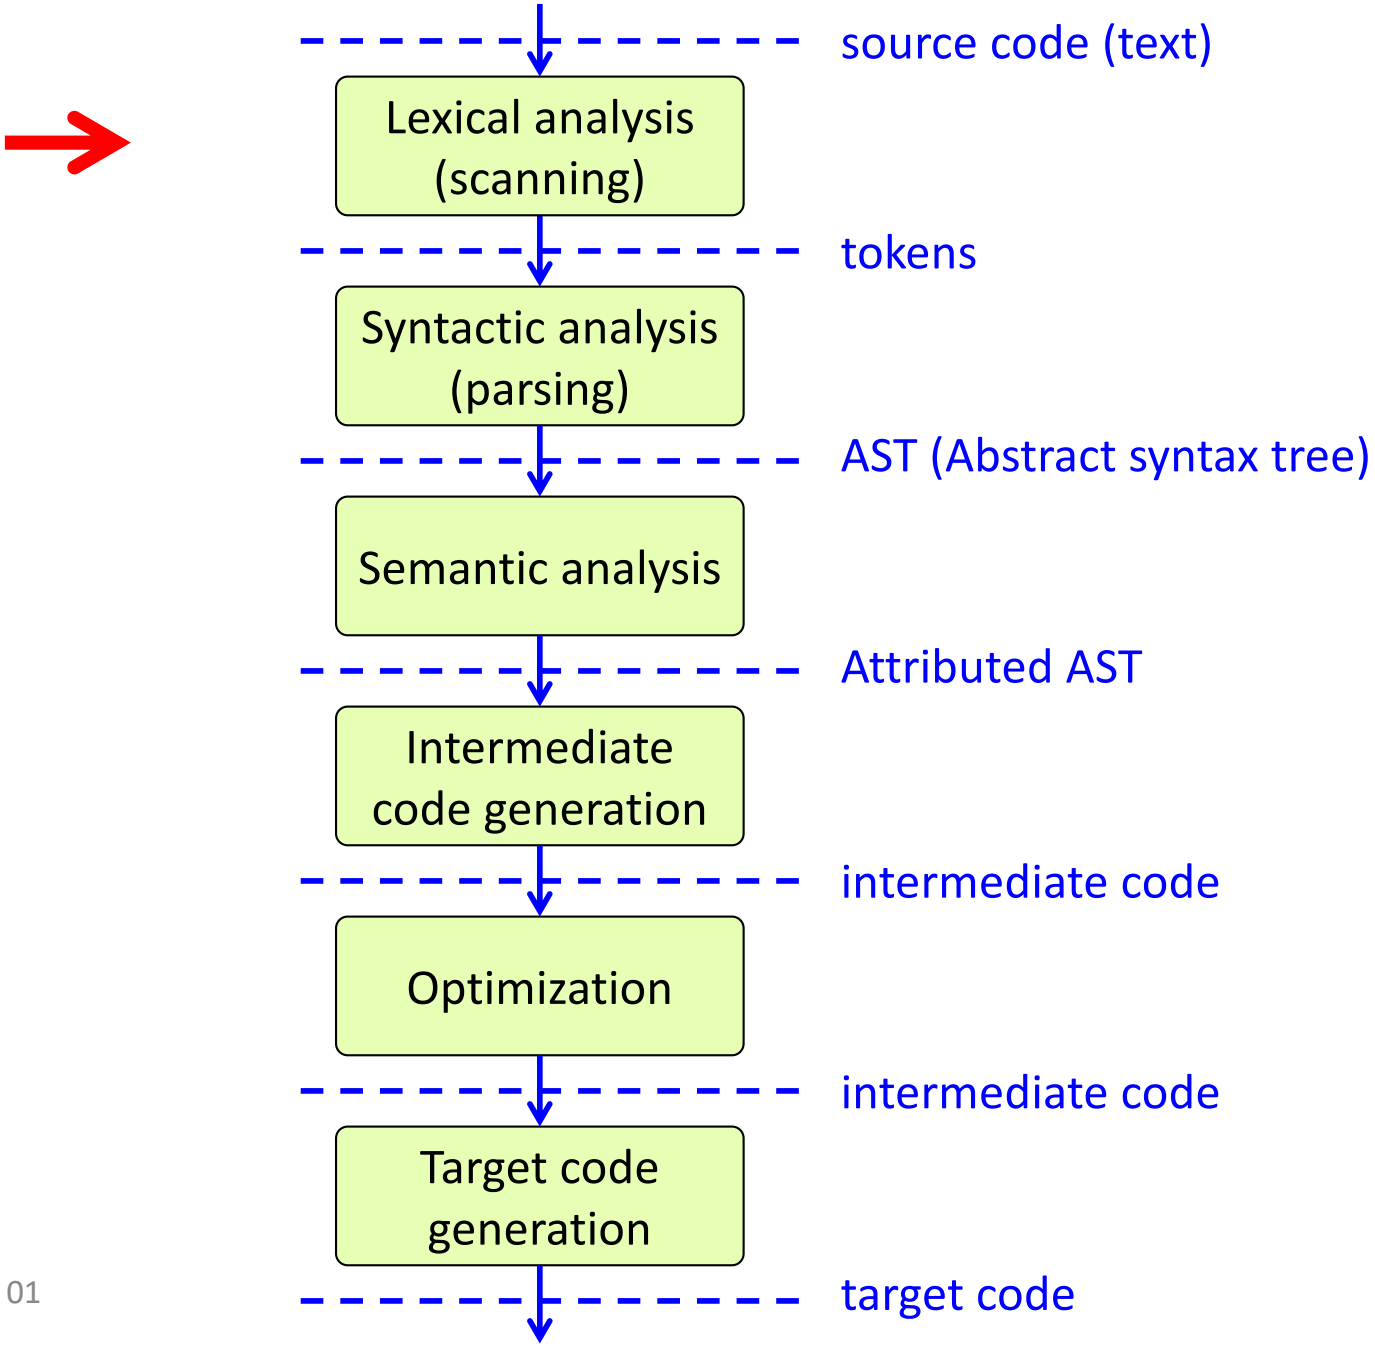
Some historical roots

- The first compiler was developed by Grace Hopper in 1952.
- John McCarthy used JIT compilation in his LISP interpreter in 1960. This was called "Compile and Go". The term JIT came later, and was popularized with Java.
- The Pascal-P system, developed by Niklaus Wirth's group at ETH in 1972, used portable code called "p-code". A successor, UCSD-Pascal, used a variant of p-code that was byte-oriented. The UCSD interpreter was easy to port to different machines and the language spread quickly, and became a popular language taught at many universities. Java, introduced in 1994, used easily portable bytecode, and spread quickly for the same reasons.
- Smalltalk-80 used bytecode in the 1980s, and pioneered several runtime compilation and optimization techniques for object-oriented languages.
- The research language Self refined Smalltalk's dynamic optimization techniques during the early 1990s. This work laid the foundation for the dynamically optimizing VMs we use today, like the Java Hotspot VM, the Javascript V8 VM, and many others.

Compiler phases and program representations:



Compiler phases and program representations:



Lexical analysis (scanning)

Source text:

```
while (k<=n) {
  sum=sum+k;
  k=k+1;
}
```

Lexical analysis (scanning)

Source text:

```
while (k<=n) {
  sum=sum+k;
  k=k+1;
}
```

What the file looks like:

```
while (k<=n) {\n  sum=sum+k;\n  k=k+1;\n}
```

Lexical analysis (scanning)

Source text:

```
while (k<=n) {
  sum=sum+k;
  k=k+1;
}
```

What the file looks like:

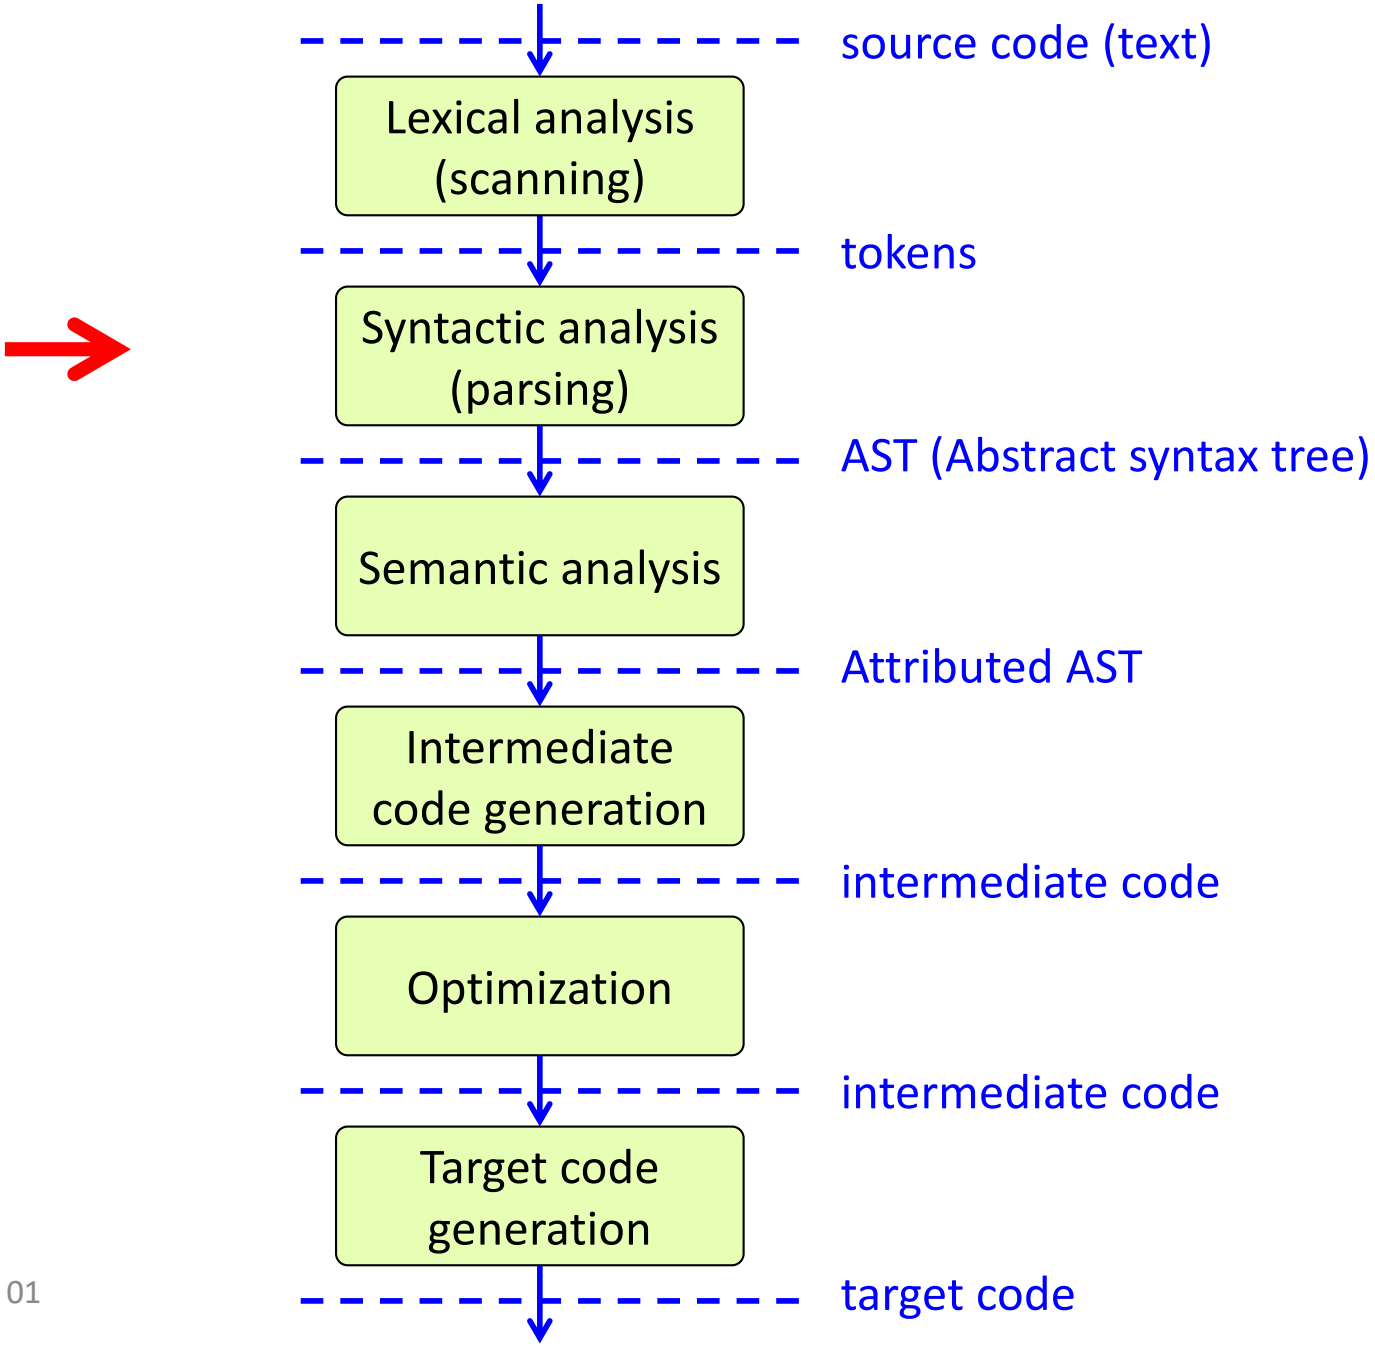
```
while (k<=n) {\n  sum=sum+k;\n  k=k+1;\n}
```

Tokens the scanner produces:

```
WHILE LPAR ID("k") LEQ ID("n") RPAR LBRA ID("sum") EQ ...
```

A *token* is a symbolic name, sometimes with an attribute.
A *lexeme* is a string corresponding to a token.
Whitespace (blanks, newlines, etc., are skipped)

Compiler phases and program representations:



Syntactic analysis (parsing)

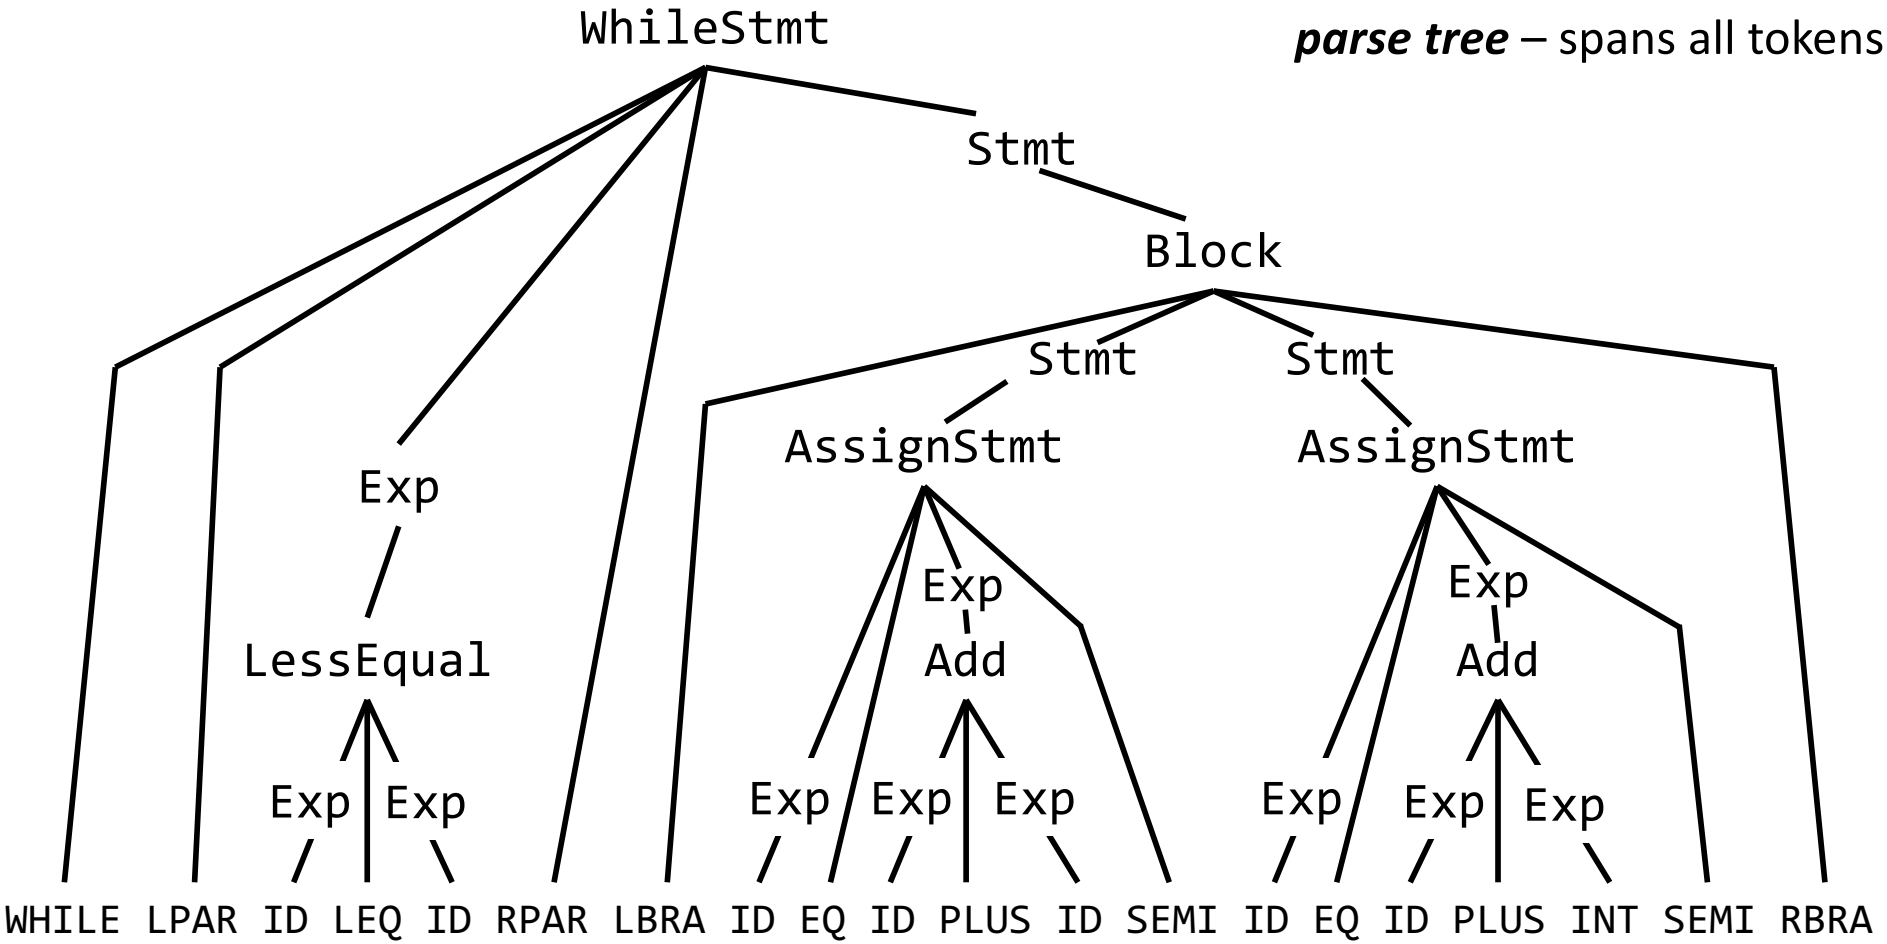
WhileStmt

parse tree – spans all tokens

```
WHILE LPAR ID LEQ ID RPAR LBRA ID EQ ID PLUS ID SEMI ID EQ ID PLUS INT SEMI RBRA
```

```
while ( k <= n ) { sum = sum + k ; k = k + 1 ; }
```

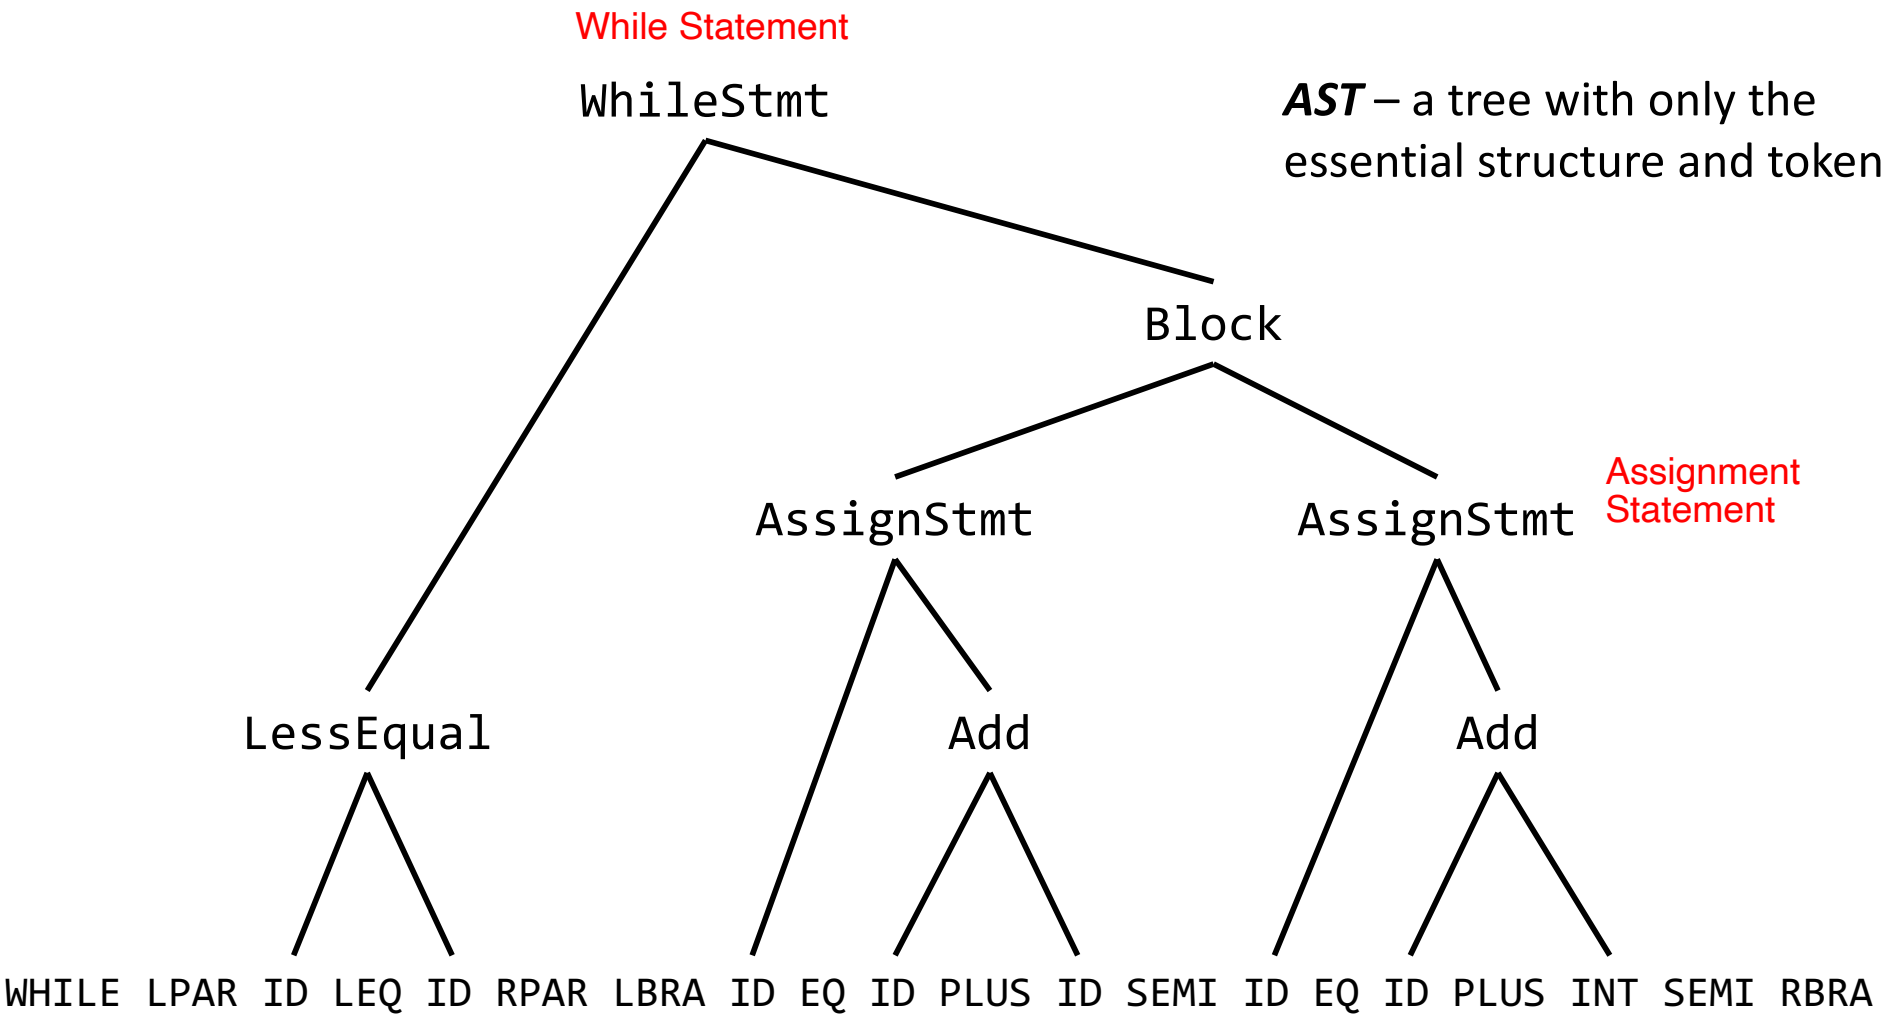
Syntactic analysis (parsing)



parse tree – spans all tokens

```
while ( k <= n ) { sum = sum + k ; k = k + 1 ; }
```

Abstract syntax tree (AST)



AST – a tree with only the essential structure and tokens

```
while ( k <= n ) { sum = sum + k ; k = k + 1 ; }
```

Abstract syntax trees

- Used inside the compiler for representing the program
- Very similar to the parse tree, but
  - contains only essential tokens
  - has a simpler more natural structure
- Often represented by a typed object-oriented model
  - abstract classes (Stmt, Expr, Decl, ...)
  - concrete classes (WhileStmt, IfStmt, Add, Sub, ...)

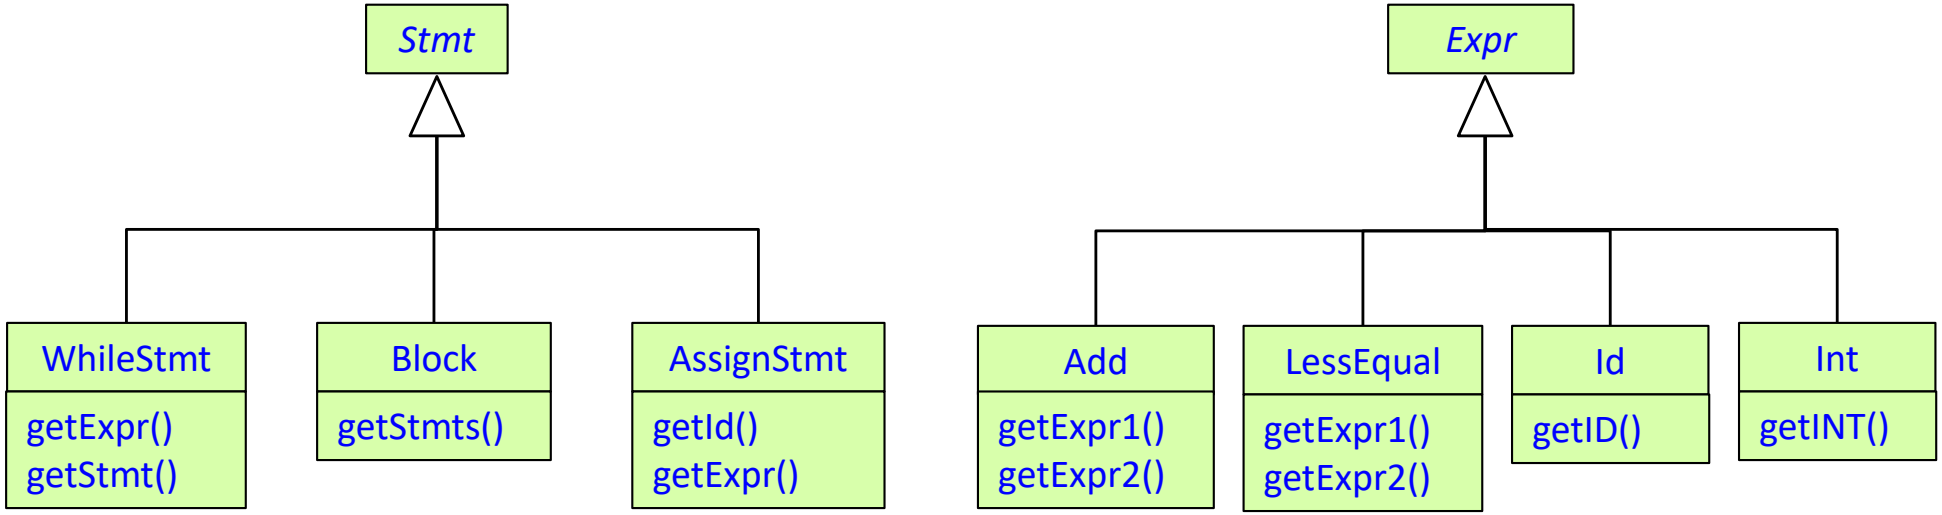
(or corresponding algebraic datatypes with constructors)

Designing an AST model

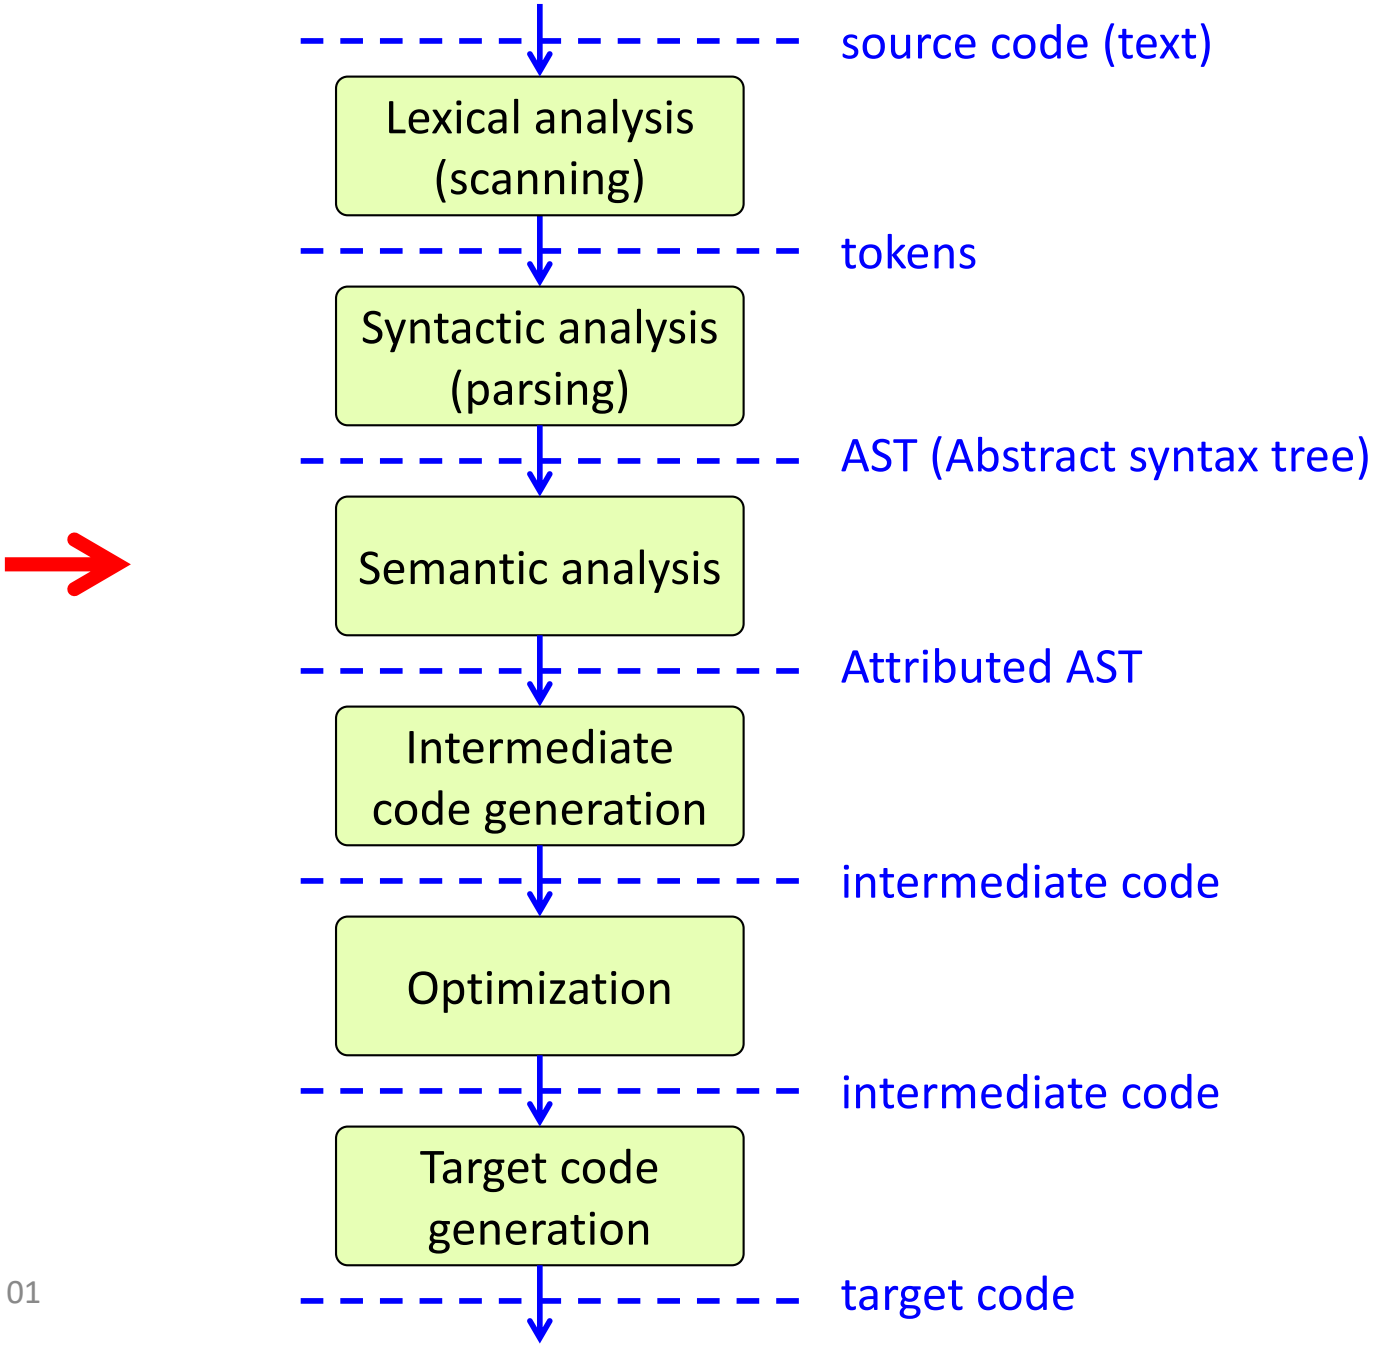
What abstract constructs are there in the language	What concrete constructs are there?	What parts do the concrete constructs have?
• OOP: Make them abstract classes • FP: Make them algebraic data types	• OOP: Make them subclasses of the abstract classes • FP: Make them constructors of the algebraic data types	• OOP: Add getters for them, to access parts • FP: Use pattern matching to access parts

Example AST class hierarchy

Example AST class hierarchy



Compiler phases and program representations:



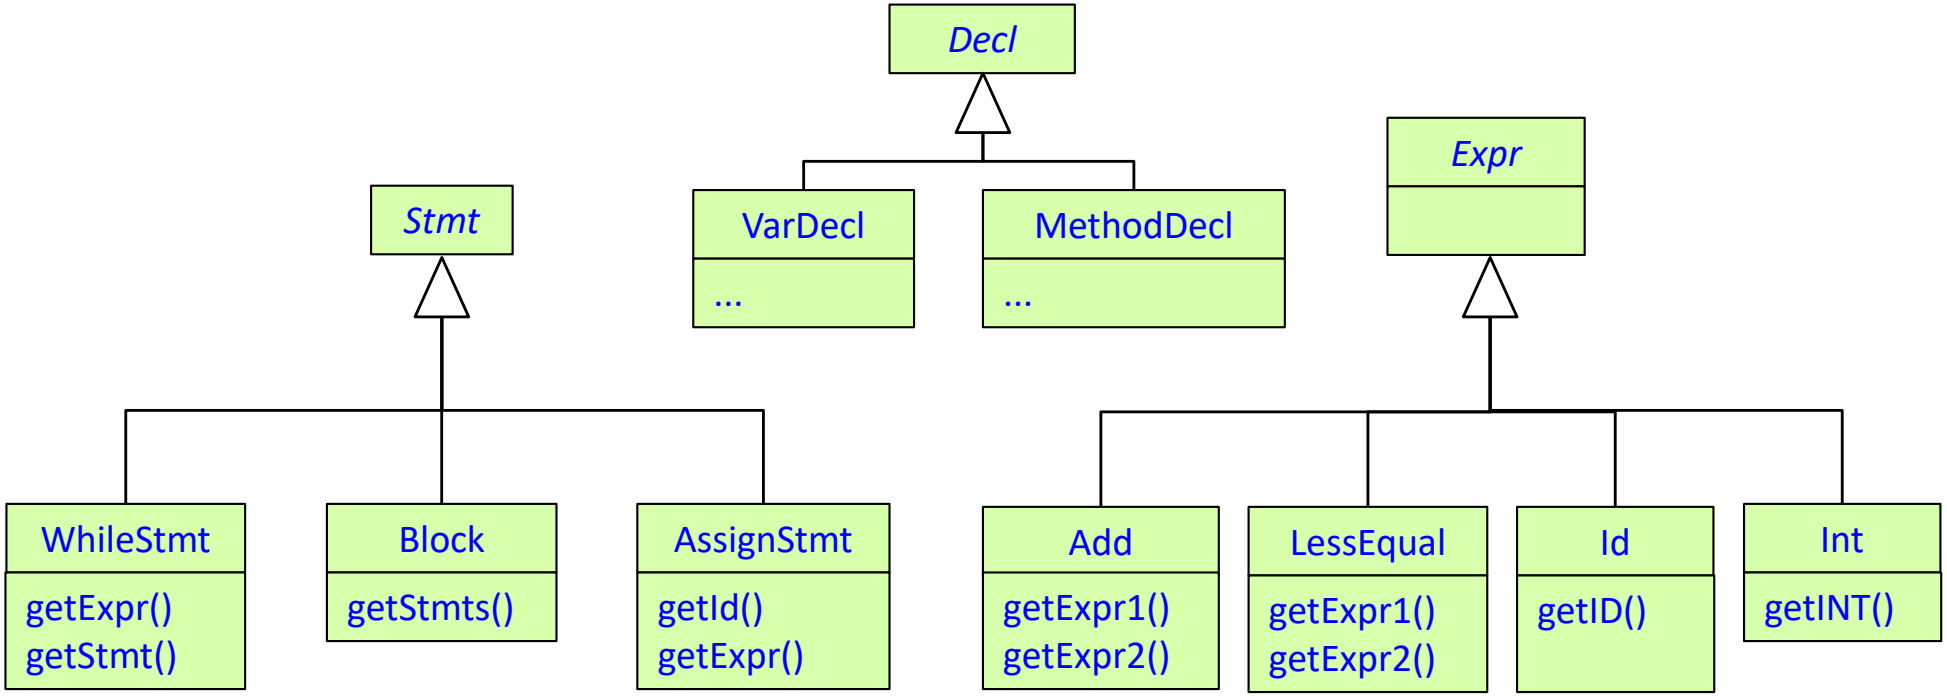
Semantic analysis

Analyze the AST, for example,

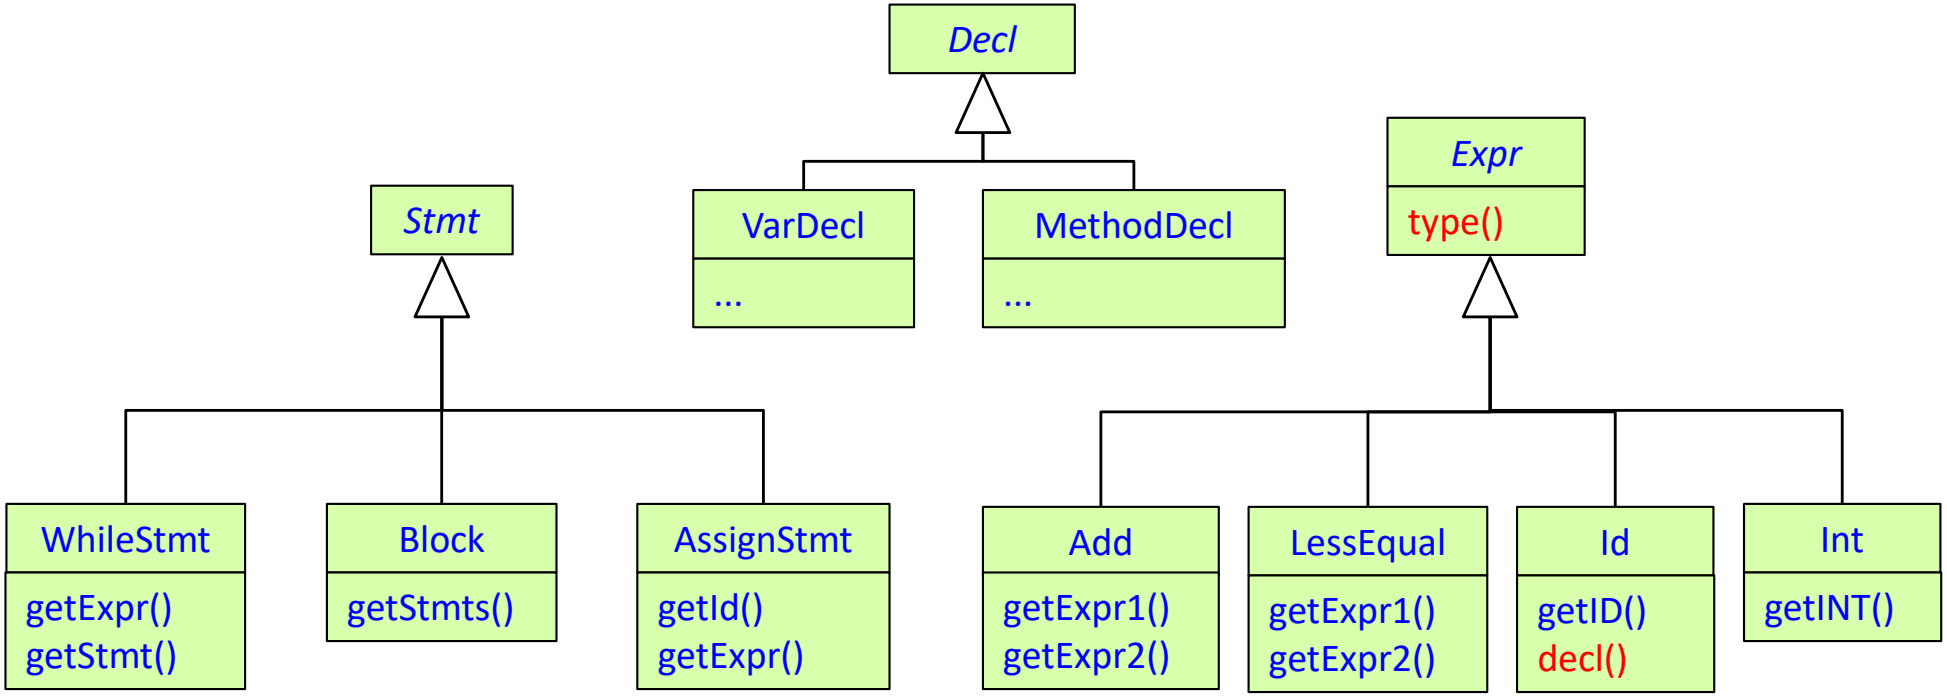
- Which declaration corresponds to a variable?
- What is the type of an expression?
- Are there compile time errors in the program?

Analysis aided by adding *attributes* to the AST (properties of AST nodes)

Example attributes

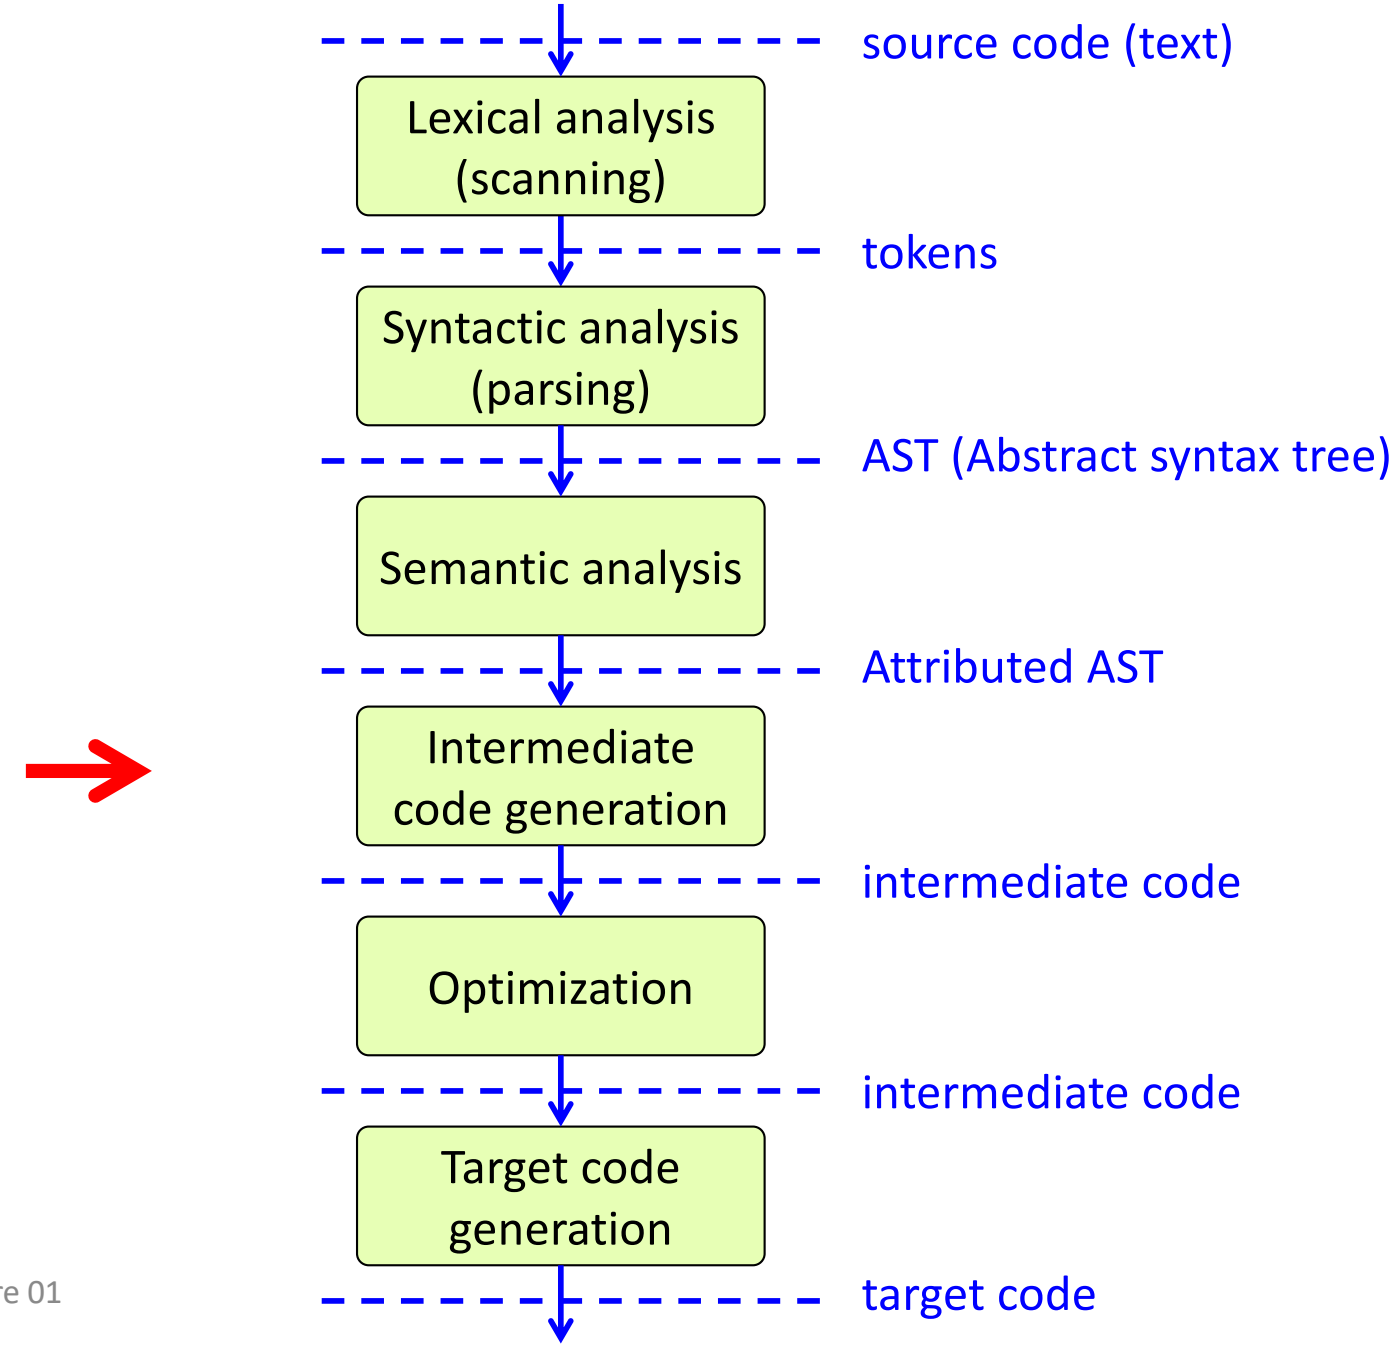


Example attributes



Each Expr has a type() attribute, indicating if the expression is integer, boolean, etc.
Each Id has a decl() attribute, referring to the appropriate declaration node.

Compiler phases and program representations:

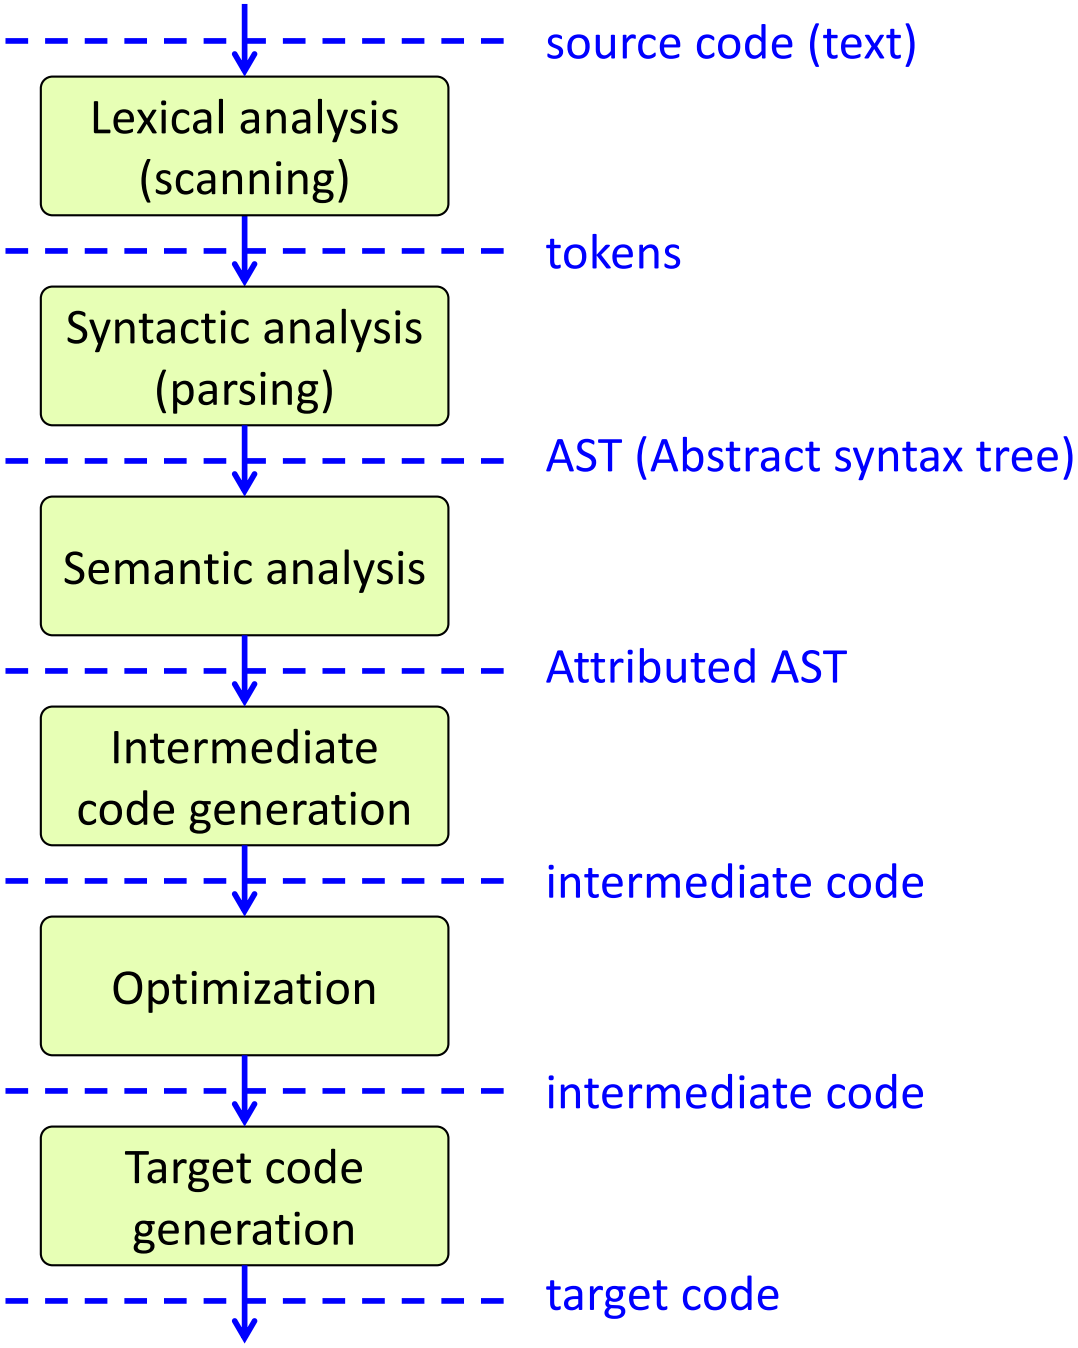


Intermediate code generation

Intermediate code:

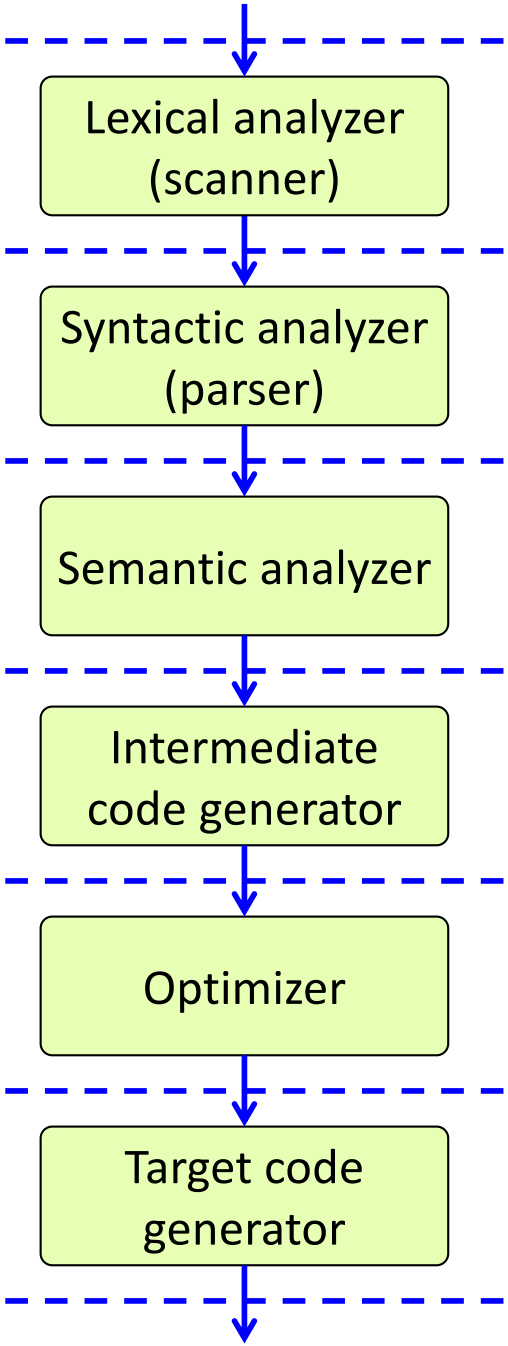
- also known as *intermediate representation* (IR)
- independent of source language
- independent of target machine
- usually assembly-like
  - but simpler, without many instruction variants
  - and with an unlimited number of registers (or uses a stack instead of registers)

Compiler phases and program representations:

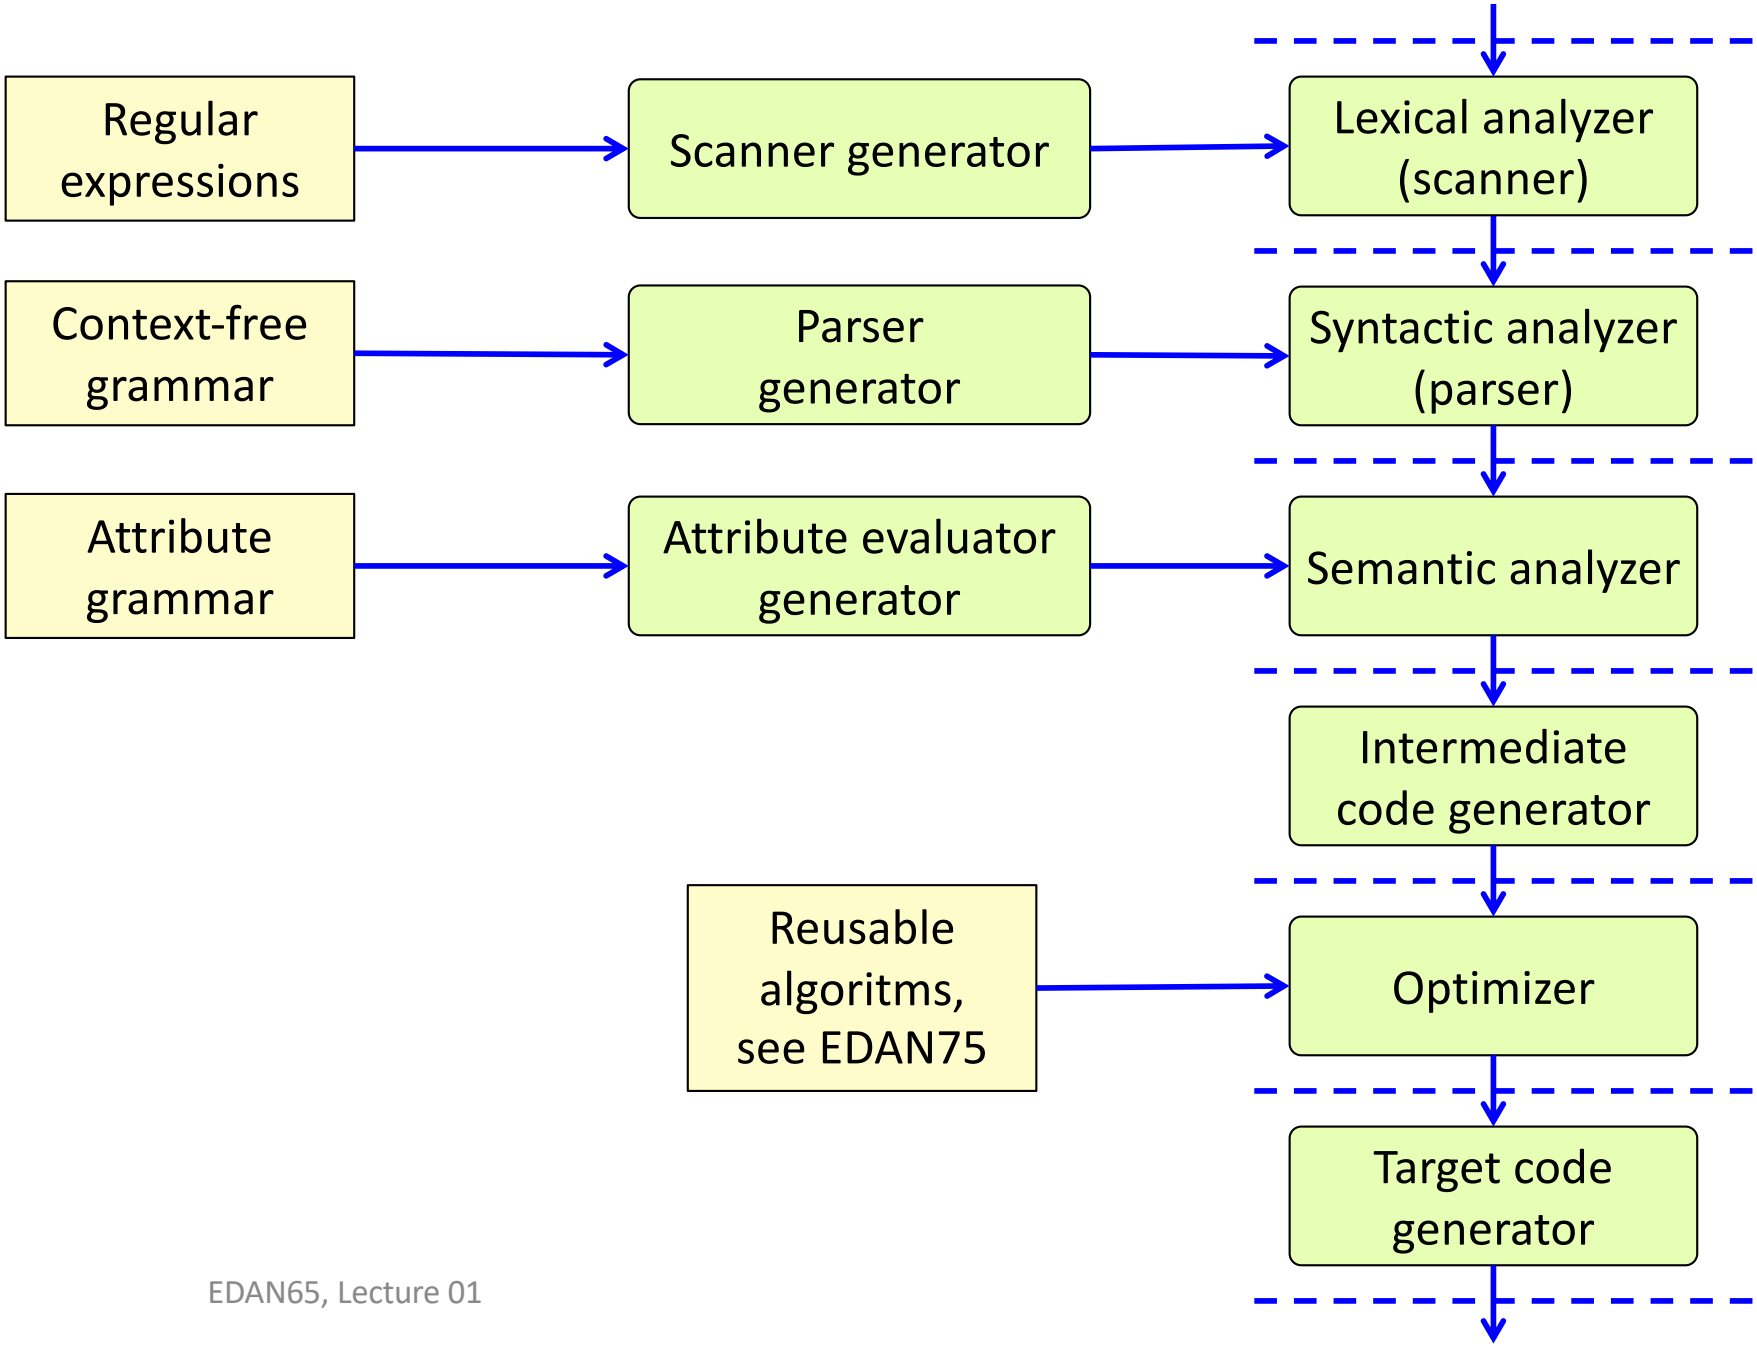


See the course Optimizing Compilers, EDAN75

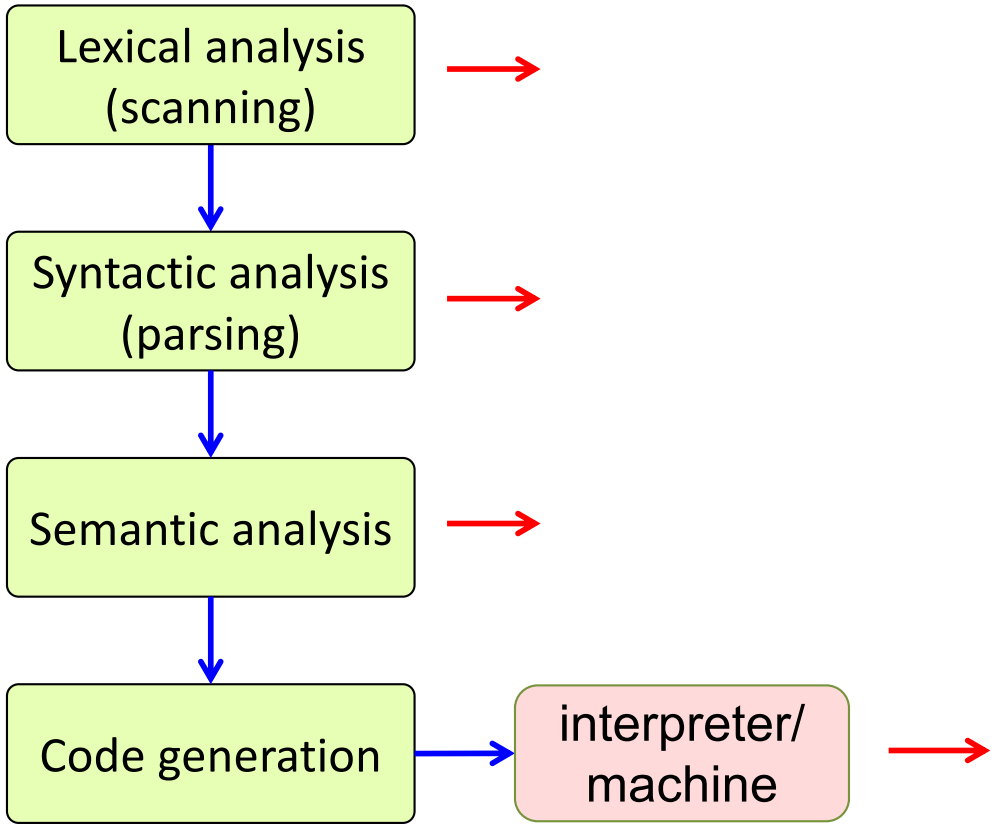
Generating the compiler:



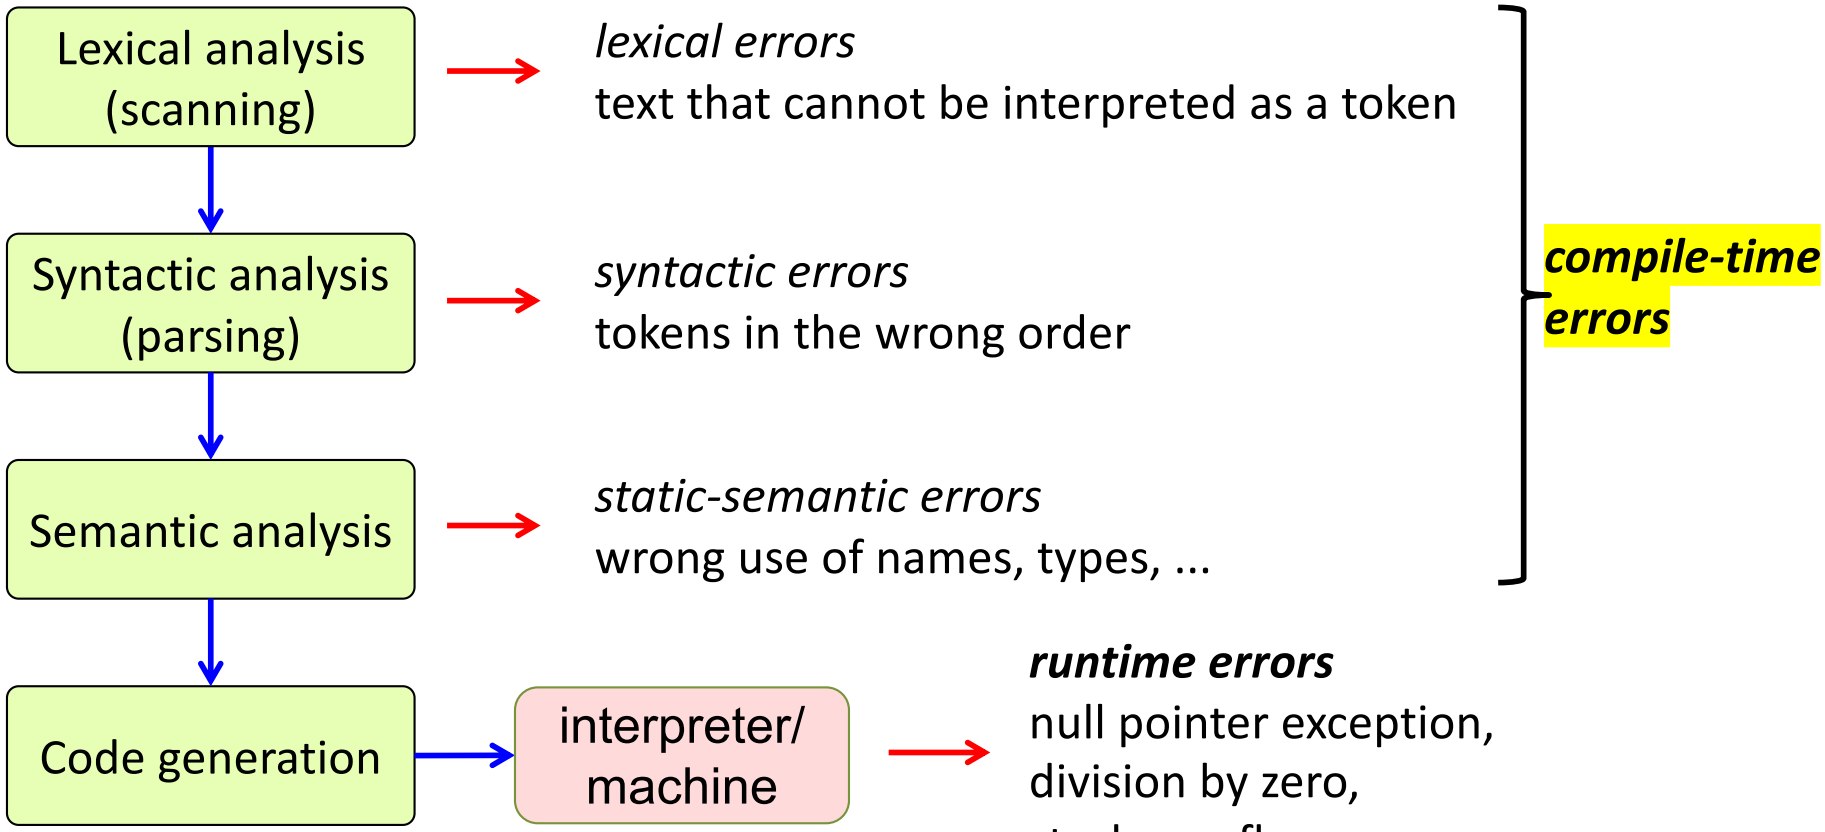
Generating the compiler:



Program errors



Program errors



logic errors

Compute the wrong result.
Not caught by the compiler or the machine.
Normally try to catch using test cases.
Assertions and program verification can also help.

What kind is each error? Lexical, Syntactic, Static-semantic, Run-time, Logic?

Example errors

1.
```
int # square(int x) {
    return x * x;
}
```

2.
```
int double square(int x) {
    return x * x;
}
```

3.
```
boolean square(int x) {
    return x * x;
}
```

4.
```
int p(int x) {
    return x / 0;
}
```

5.
```
int square(int x) {
    return 2 * x;
}
```

Example errors

Lexical error:

1.
```
int # square(int x) {
    return x * x;
}
```

Syntactic error:

2.
```
int double square(int x) {
    return x * x;
}
```

Static-semantic error:

3.
```
boolean square(int x) {
    return x * x;
}
```

Runtime error:

4.
```
int p(int x) {
    return x / 0;
}
```

Logic error:

5.
```
int square(int x) {
    return 2 * x;
}
```

Safe versus unsafe languages

- **Safe language**

  All runtime errors are caught by the generated code and/or runtime system, and are reported in terms of the language.

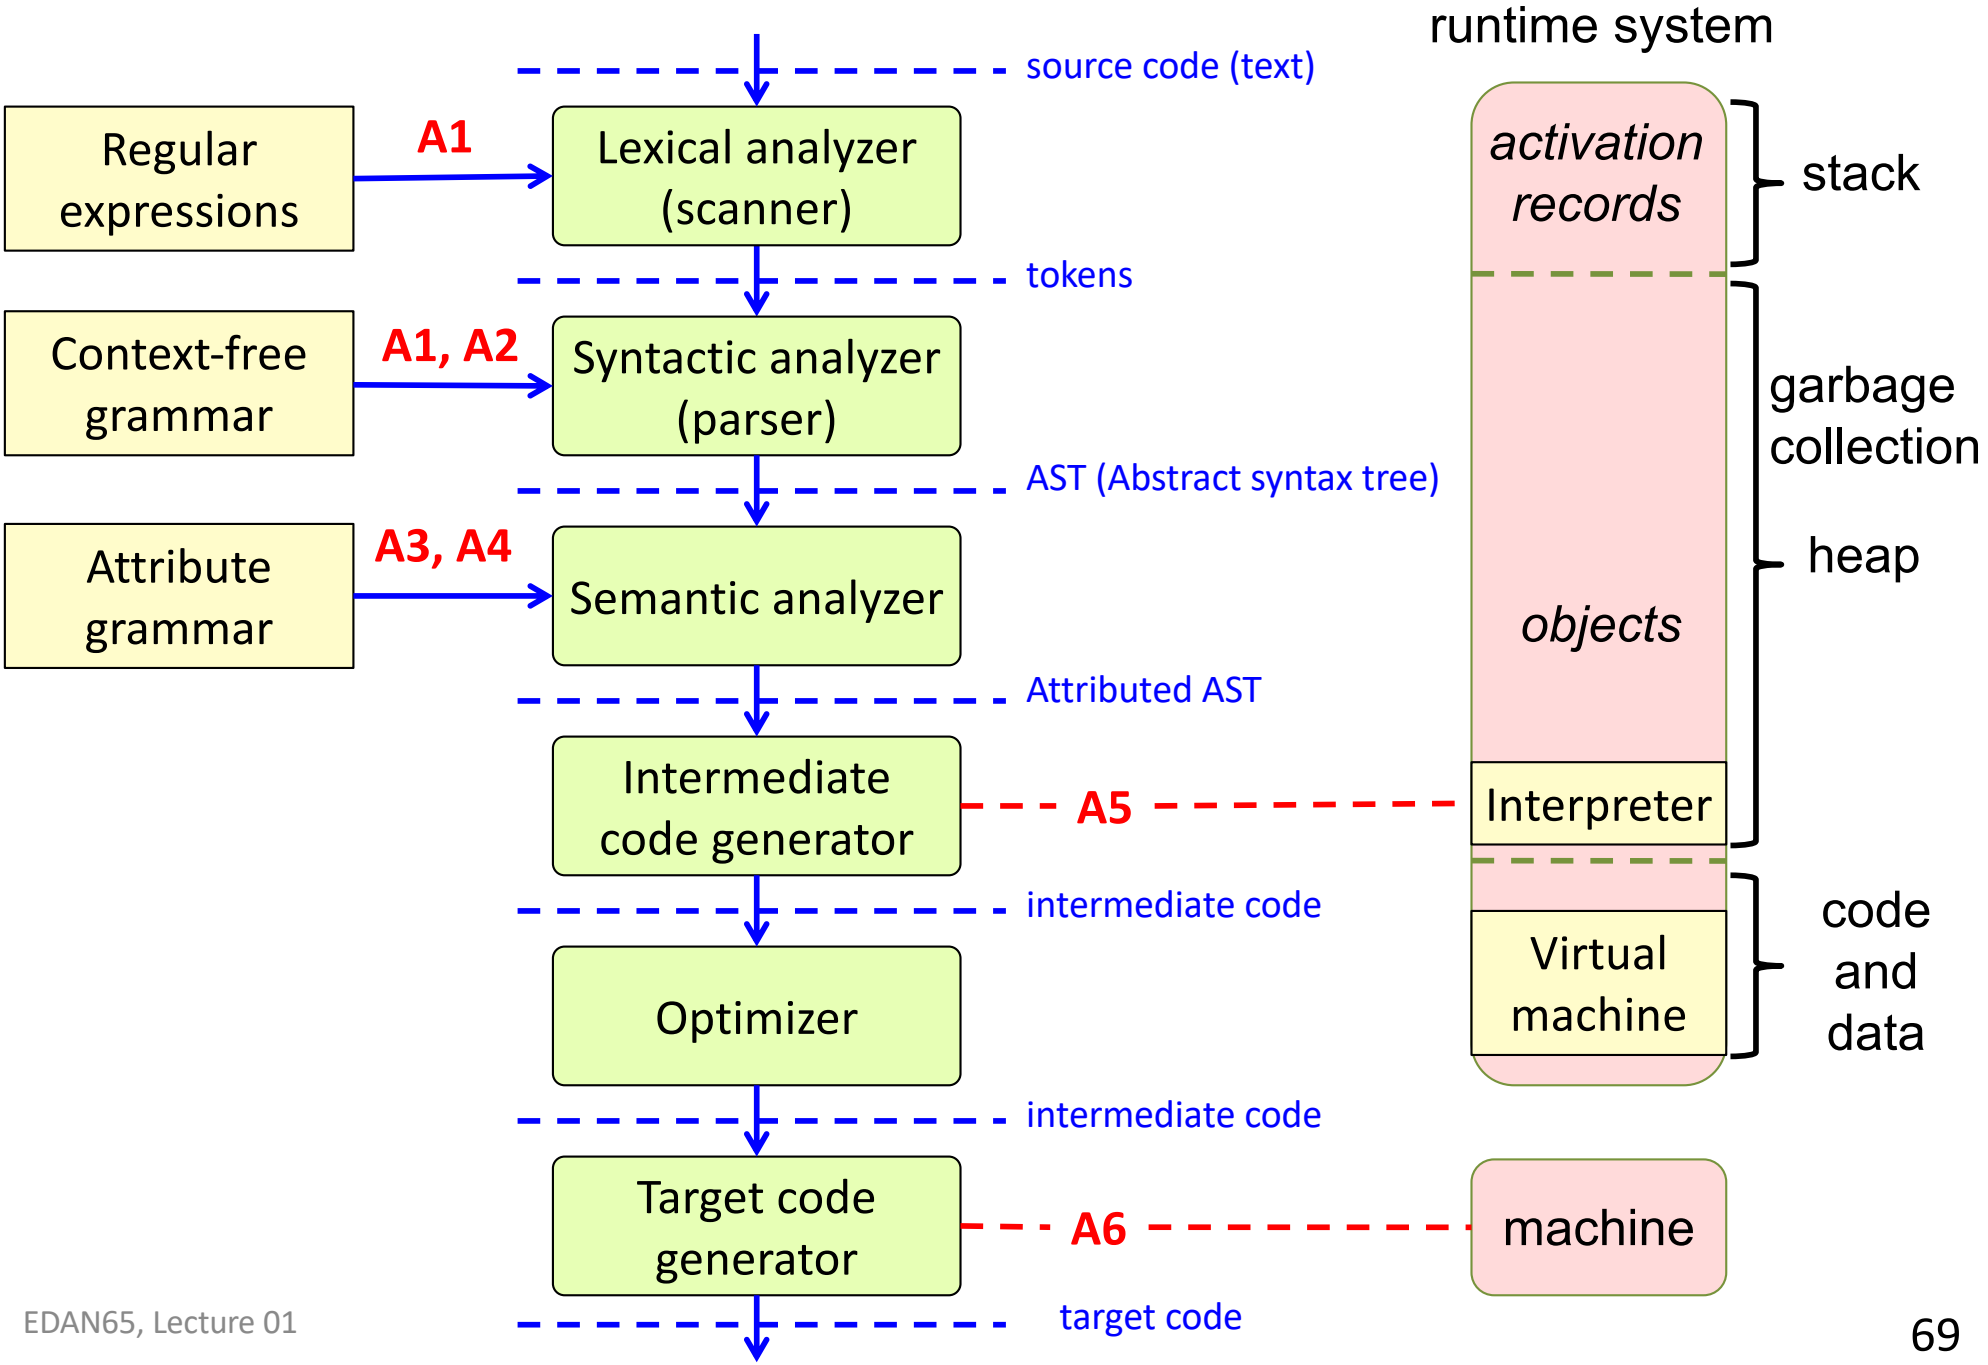
  Examples: Java, C#, Smalltalk, Python, ...

- **Unsafe language**

  Runtime errors in the generated code can lead to undefined behavior, for example an out of bounds array access. In the best case, this gives a hardware exception soon after the real error, stopping the program ("segmentation fault"). In the worst case, the execution continues, computing the wrong result or giving a segmentation fault much later, leading to bugs that can be extremely hard to find.

  Examples: C, Assembly

Course overview



After this course...

- You will have built a complete compiler
- You will have seen new declarative ways of programming
- You will have learnt some fundamental computer science theory
- You will have experience from using several practical tools

Some related courses

- EDAN70, **Project in Computer Science**, lp2
  - Build a small tool, evaluate it, write a short paper
- EDAP15, **Program Analysis**, lp3
  - Deeper program analysis for e.g., security, quality, program understanding, software improvement, ...
- EDAN75, **Optimizing compilers**, lp3
  - Algorithms for optimizing assembly level code

- **Master's thesis project** in compilers (related to research or industry)

Applications of compiler construction

- Traditional compilers from source to assembly
- Source-to-source translators, transpilers, preprocessors
- Interpreters and virtual machines
- Integrated programming environments
- Program analysis tools
- Refactoring and other program transformation tools
- Domain-specific languages

Examples of Domain-Specific Languages

Some related research at LTH

Language tools

- Extensible compiler tools (Görel Hedin)
- Program analysis, software tools (Christoph Reichenbach)
- Adaptive developer tools (Emma Söderberg)

Backend

- Real-time garbage collection (Roger Henriksson)
- Code optimization for multiprocessors (Jonas Skeppstedt)

NLP

- Natural language processing (Pierre Nugues)

Domain-specific languages

- Languages for robotics (Volker Krüger, Christoph Reichenbach)
- Languages for requirements modeling (Björn Regnell)
- Languages for simulation and control (The control department)

Summary questions

- What are the major compiler phases?
- What is the difference between the analysis and synthesis phases?
- Why do we use intermediate code?
- What is the advantage of separating the front and back ends?
- What is
  - a lexeme?
  - a token?
  - a parse tree?
  - an abstract syntax tree?
  - intermediate code?
- What is the difference between assembly code, object code, and executable code?
- What is bytecode, an interpreter, a virtual machine?
- What is a JIT compiler?
- What kind of errors can be caught by a compiler? A runtime system?

See course website https://cs.lth.se/edan65 for what to do this week.
